

# Package ‘GeneNet’

November 14, 2021

**Version** 1.2.16

**Date** 2021-11-14

**Title** Modeling and Inferring Gene Networks

**Author** Juliane Schaefer, Rainer Opgen-Rhein, and  
Korbinian Strimmer.

**Maintainer** Korbinian Strimmer <strimmerlab@gmail.com>

**Depends** R (>= 3.0.2), corpcor (>= 1.6.10), longitudinal (>= 1.1.13),  
fdrtool (>= 1.2.17)

**Suggests** graph, Rgraphviz

**Imports** stats, grDevices

**Description** Analyzes gene expression  
(time series) data with focus on the inference of gene networks.  
In particular, GeneNet implements the methods of Schaefer and  
Strimmer (2005a,b,c) and Opgen-Rhein and Strimmer (2006, 2007)  
for learning large-scale gene association networks (including  
assignment of putative directions).

**License** GPL (>= 3)

**URL** <https://strimmerlab.github.io/software/genenet/>

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2021-11-14 18:10:01 UTC

GeneNet-package	<i>The GeneNet package</i>
-----------------	----------------------------

---

### Description

GeneNet is a package for analyzing gene expression (time series) data with focus on the inference of gene networks. In particular, GeneNet implements the methods of Sch" afer and Strimmer (2005a,b,c) and Opgen-Rhein and Strimmer (2006, 2007) for learning large-scale gene association networks (including assignment of putative directions).

### Author(s)

Juliane Sch" afer, Rainer Opgen-Rhein, and Korbinian Strimmer (<https://strimmerlab.github.io/>)

### See Also

---

arth800	<i>Time Series Expression Data for 800 Arabidopsis Thaliana Genes</i>
---------	---

---

### Description

This data set describes the temporal expression of 800 genes of *A. thaliana* during the diurnal cycle. The 800 genes are a subset of the data presented in Smith et al. (2004) and were selected for periodicity according to the method implemented in the R package GeneCycle (<https://cran.r-project.org/package=GeneCycle>).

### Usage

```
data(arth800)
```

### Format

`arth800.expr` is a [longitudinal](#) object with repetitions, and contains the log2 transformed expression data.

`arth800.mexpr` is a [longitudinal](#) object, and contains the mean expression levels of `arth800.expr`.

`arth800.descr`, `arth800.name`, `arth800.probe`, `arth800.symbol` are vectors containing additional information about each gene.

**Source**

The microarray experiments were performed in the laboratory of S. Smith (Edinburgh). The data are available from the NASCArrays database under experiment reference number NASCARRAYS-60.

**References**

Smith et al. 2004. Diurnal changes in the transcriptome encoding enzymes of starch metabolism provide evidence for both transcriptional and posttranscriptional regulation of starch metabolism in Arabidopsis leaves. *Plant Physiol.* 136: 2687-2699

**Examples**

```
# load GeneNet library
library("GeneNet")

# load data set
data(arth800)

is.longitudinal(arth800.expr)
summary(arth800.expr)

# plot first nine time series
plot(arth800.expr, 1:9)
```

---

cor0.test

*Test of Vanishing (Partial) Correlation*

---

**Description**

cor0.test computes a p-value for the two-sided test with the null hypothesis  $H_0: \rho = 0$  versus the alternative hypothesis  $H_A: \rho \neq 0$ .

If method="student" is selected then the statistic  $t = r \sqrt{(\kappa - 1) / (1 - r^2)}$  is considered which under  $H_0$  is student-t distributed with  $df = \kappa - 1$ . This method is exact.

If method="dcor0" is selected then the p-value is computed directly from the null distribution of the (partial) correlation (see [dcor0](#)). This method is also exact.

If method="ztransform" is selected then the p-value is computed using the z-transform (see [z.transform](#)), i.e. using a suitable chosen normal distribution. This method returns approximate p-values.

**Usage**

```
cor0.test(r, kappa, method=c("student", "dcor0", "ztransform"))
```

**Arguments**

r	observed correlation
kappa	degree of freedom of the null-distribution
method	method used to compute the p-value

**Value**

A p-value.

**Author(s)**

Juliane Sch\"afer and Korbinian Strimmer (<https://strimmerlab.github.io>).

**See Also**

[dcor0](#), [kappa2n](#), [z.transform](#).

**Examples**

```
# load GeneNet library
library("GeneNet")

# covariance matrix
m.cov <- rbind(
  c(3,1,1,0),
  c(1,3,0,1),
  c(1,0,2,0),
  c(0,1,0,2)
)

# compute partial correlations
m.pcor <- cor2pcor(m.cov)
m.pcor

# corresponding p-values
# assuming a sample size of 25, i.e. kappa=22
kappa2n(22, 4)
cor0.test(m.pcor, kappa=22)
cor0.test(m.pcor, kappa=22) < 0.05

# p-values become smaller with larger r
cor0.test(0.7, 12)
cor0.test(0.8, 12)
cor0.test(0.9, 12)

# comparison of various methods
cor0.test(0.2, 45, method="student")
cor0.test(0.2, 45, method="dcor0")
cor0.test(0.2, 45, method="ztransform")
```

## Description

This data set describes the temporal expression of 102 genes of *E. Coli* after induction of the expression of SOD (recombinant human superoxide dismutase).

## Usage

```
data(ecoli)
```

## Format

caulobacter is a `longitudinal` object containing the data from the Schmidt-Heck et al. (2004) experiment. Essentially, this is a matrix with 102 columns (=genes) and 9 rows (=time points). All expression levels are given in log<sub>2</sub>-ratios with respect to the first time point (i.e. the induction at time 0).

## Source

The microarray experiment was performed at the Institute of Applied Microbiology, University of Agricultural Sciences of Vienne. The data and the experiment is described in Schmidt-Heck et al. (2004).

## References

Schmidt-Heck, W., Guthke, R., Toepfer, S., Reischer, H., Duerrschmid, K., and Bayer, K. (2004) Reverse engineering of the stress response during expression of a recombinant protein. In: *Proceedings of the EUNITE 2004 European Symposium on Intelligent Technologies, Hybrid Systems and their Implementation on Smart Adaptive Systems, June 10-12, 2004, Aachen, Germany*, Verlag Mainz, Wissenschaftsverlag, Aachen, 2004, 407-441 (ISBN 3-86130-368-X).

## Examples

```
# load GeneNet library
library("GeneNet")

# load data set
data(ecoli)
is.longitudinal(ecoli)

# how many samples and how many genes?
dim(ecoli)
summary(ecoli)
get.time.repeats(ecoli)

# plot first nine time series
plot(ecoli, 1:9)
```

---

ggm.estimate.pcor      *Graphical Gaussian Models: Small Sample Estimation of Partial Correlation*

---

## Description

ggm.estimate.pcor offers an interface to two related shrinkage estimators of partial correlation. Both are fast, statistically efficient, and can be used for analyzing small sample data.

The default method "statics" employs the function `pcor.shrink` whereas the "dynamic" method relies on `dyn.pcor` (in the longitudinal package). The difference between the two estimators is that the latter takes the spacings between time points into account if the input are multiple time course data (these must be provided as `longitudinal` object).

## Usage

```
ggm.estimate.pcor(x, method = c("static", "dynamic"), ...)
```

## Arguments

x	data matrix (each rows corresponds to one multivariate observation)
method	method used to estimate the partial correlation matrix. Available options are "static" (the default) and "dynamic" - both are shrinkage methods.
...	options passed to <code>pcor.shrink</code> and to <code>dyn.pcor</code> (in the longitudinal package).

## Details

For details of the shrinkage estimators we refer to Opgen-Rhein and Strimmer (2006a,b) and Sch\"afer and Strimmer (2005), as well as to the manual pages of `pcor.shrink` (in the corpcor package) and `dyn.pcor` (in the longitudinal package).

Previously, this function offered several further options. The old option called "shrinkage" corresponds to the present "static" option. The other old options "observed.pcor", "partial.bagged.cor", and "bagged.pcor" are now considered obsolete and have been removed.

## Value

An estimated partial correlation matrix.

## Author(s)

## Examples

```
## Not run:

# load GeneNet library
library("GeneNet")

# generate random network with 40 nodes
# it contains 780=40*39/2 edges of which 5 percent (=39) are non-zero
true.pcor <- ggm.simulate.pcor(40)

# simulate data set with 40 observations
m.sim <- ggm.simulate.data(40, true.pcor)

# simple estimate of partial correlations
estimated.pcor <- cor2pcor( cor(m.sim) )

# comparison of estimated and true values
sum((true.pcor-estimated.pcor)^2)

# a slightly better estimate ...
estimated.pcor.2 <- ggm.estimate.pcor(m.sim)
sum((true.pcor-estimated.pcor.2)^2)

## End(Not run)
```

## Description

ggm.simulate.data takes a positive definite partial correlation matrix and generates an i.i.d. sample from the corresponding standard multinormal distribution (with mean 0 and variance 1). If the input matrix pcor is not positive definite an error is thrown.

## Usage

```
ggm.simulate.data(sample.size, pcor)
```

## Arguments

sample.size	sample size of simulated data set
pcor	partial correlation matrix

## Value

A multinormal data matrix.

true.pcor <- ggm.simulate.pcor(40)

# simulate data set with 40 observations
m.sim <- ggm.simulate.data(40, true.pcor)

# simple estimate of partial correlations
estimated.pcor <- cor2pcor( cor(m.sim) )

# comparison of estimated and true values
sum((true.pcor-estimated.pcor)^2)

# a slightly better estimate ...
```

```
estimated.pcor.2 <- ggm.estimate.pcor(m.sim)
sum((true.pcor-estimated.pcor.2)^2)
```

---

ggm.simulate.pcor      *Graphical Gaussian Models: Simulation of Networks*

---

## Description

ggm.simulate.pcor generates a random matrix of partial correlations that corresponds to a GGM network of a given size (num.nodes) with a specified fraction of non-zero edges. The diagonal entries of the output matrix contain 1.

If stdprec=TRUE then the standardised precision matrix is returned instead of the matrix of partial correlations.

## Usage

```
ggm.simulate.pcor(num.nodes, etaA=0.05, stdprec=FALSE)
```

## Arguments

num.nodes	number of nodes in the network
etaA	fraction of edges with non-zero partial correlation (default: 0.05)
stdprec	return standardised precision matrix, rather than matrix of partial correlations

## Details

The simulation of the partial correlation matrix works by generating a diagonally dominant matrix as a positive definite precision matrix (inverse covariance matrix), which is subsequently standardized and transformed into the matrix of partial correlations. For the full algorithm see Sch" afer and Strimmer (2005).

## Value

A positive partial correlation matrix (diagonal 1) with positive definite underlying precision matrix.

If stdprec=TRUE then the standardised precision matrix is returned instead.

## Author(s)

Juliane Sch" afer and Korbinian Strimmer (<https://strimmerlab.github.io>).

---

kappa2n

*Relationship Between Sample Size and the Degree of Freedom of Correlation Distribution*

---

**Description**

The function kappa2n returns the sample size that corresponds to a given degree of freedom kappa, whereas n2kappa converts sample size to the corresponding degree of freedom.

**Usage**

```
kappa2n(kappa, p=2)
n2kappa(n, p=2)
```

**Arguments**

kappa	degree of freedom
p	number of variables (p=2 corresponds to simple correlation)
n	sample size

**Details**

The degree of freedom  $\kappa$  of the sample distribution of the empirical correlation coefficient depends both on the sample size  $n$  and the number  $p$  of investigated variables, i.e. whether simple or partial correlation coefficients are being considered. For  $p=2$  (simple correlation coefficient) the degree of freedom equals  $\kappa = n-1$ , whereas for arbitrary  $p$  (with  $p-2$  variables eliminated in the partial correlation coefficient)  $\kappa = n-p+1$  (see also [dcor0](#)).

**Value**

The sample size  $n$  corresponding to a given  $\kappa$ , or the degree of freedom  $\kappa$  corresponding to a given  $p$ .

**Author(s)**

Juliane Sch" afer and Korbinian Strimmer (<https://strimmerlab.github.io>).

**See Also**

[dcor0](#).

**Examples**

```
# load GeneNet library
library("GeneNet")

# sample sizes corresponding to kappa=7
kappa2n(7)      # simple correlation
kappa2n(7, 40) # partial correlation with p=40 variables

# degree of freedom corresponding to n=100
n2kappa(100)
n2kappa(100, 40)
```

---

network.make.graph      *Graphical Gaussian Models: Plotting the Network*

---

**Description**

`network.make.dot` converts an edge list as obtained by [network.test.edges](#) into a "dot" file that can directly be used for plotting the network with `graphviz`.

`network.make.graph` converts an edge list as obtained by [network.test.edges](#) into a graph object.

`edge.info` shows the edge weights and the edge directions.

`node.degree` shows number of edges connected to a node (bi-directional/undirected edges are counted only once).

`num.nodes` shows the number of nodes.

## Usage

```
network.make.dot(filename, edge.list, node.labels, main=NULL, show.edge.labels=FALSE)
network.make.graph(edge.list, node.labels, drop.singles=FALSE)
edge.info(gr)
node.degree(gr)
num.nodes(gr)
```

## Arguments

filename	name of file containing the "dot" commands for graphviz
edge.list	a data frame, as obtained by <a href="#">network.test.edges</a> , listing all edges to be included in the graph
node.labels	a vector with labels for each node (will be converted to type character)
main	title included in plot
show.edge.labels	plot correlation values as edge labels (default: FALSE)
drop.singles	remove unconnected nodes
gr	a graph object

## Details

For network plotting the software "graphviz" is employed (<https://www.graphviz.org>).

For the functions `network.plot.graph` and `network.make.graph` the "graph" and "Rgraphviz" packages from the Bioconductor project (<https://www.bioconductor.org>) is required.

## Value

`network.make.dot` produces a "dot" network description file that can directly be fed into graphviz in order to produce a plot of a network.

`network.make.graph` returns a graph object, suitable for plotting with functions from the "Rgraphviz" library.

`edge.info` returns a list containing vector of weights for all edges contained in a graph, and a vector listing the directions of the edges (using Rgraphviz conventions "forward" for directed edge, and "none" for bi-directional/undirected edge).

`num.nodes` returns the number of nodes.

## Author(s)

Juliane Schläfer, Rainer Opgen-Rhein, and Korbinian Strimmer (<https://strimmerlab.github.io>).

## See Also

[network.test.edges](#), `plot.graph`.

**Examples**

```

# load GeneNet library
library("GeneNet")

# generate random network with 20 nodes and 10 percent edges (=19 edges)
true.pcor <- ggm.simulate.pcor(20, 0.1)

# convert to edge list
test.results <- ggm.list.edges(true.pcor)[1:19,]

##### use graphviz directly to produce a plot #####

# uncomment for actual use!

# nlab <- LETTERS[1:20]
# ggm.make.dot(filename="test.dot", test.results, nlab, main = "A graph")
# system("fdp -T svg -o test.svg test.dot") # SVG format

##### use Rgraphviz produce a plot #####

# uncomment for actual use!

# nlab <- LETTERS[1:20]
# gr <- network.make.graph( test.results, nlab)
# gr
# num.nodes(gr)
# edge.info(gr)
# gr2 <- network.make.graph( test.results, nlab, drop.singles=TRUE)
# gr2
# num.nodes(gr2)
# edge.info(gr2)

# plot network
# NOTE: this requires the installation of the "Rgraphviz" library
# library("Rgraphviz")
# plot(gr, "fdp")
# plot(gr2, "fdp")

## for a full example with beautified Rgraphviz plot see
## the example scripts provide with GeneNet (e.g. arabidopis-net.R)

```

**Description**

`network.test.edges` returns a data frame containing all edges listed in order of the magnitude of the partial correlation associated with each edge. If `fdr=TRUE` then in addition the p-values, q-values and posterior probabilities ( $=1 - \text{local fdr}$ ) for each potential edge are computed.

`extract.network` returns a data frame with a subset of significant edges.

**Usage**

```
network.test.edges(r.mat, fdr=TRUE, direct=FALSE, plot=TRUE, ...)
extract.network(network.all, method.ggm=c("prob", "qval", "number"),
  cutoff.ggm=0.8, method.dir=c("prob", "qval", "number", "all"),
  cutoff.dir=0.8, verbose=TRUE)
```

**Arguments**

<code>r.mat</code>	matrix of partial correlations
<code>fdr</code>	estimate q-values and local fdr
<code>direct</code>	compute additional statistics for obtaining a partially directed network
<code>plot</code>	plot density and distribution function and (local) fdr values
<code>...</code>	parameters passed on to <a href="#">fdrtool</a>
<code>network.all</code>	list with partial correlations and fdr values for all potential edges (i.e. the output of <code>network.test.edges</code> )
<code>method.ggm</code>	determines which criterion is used to select significant partial correlations (default: prob)
<code>cutoff.ggm</code>	default cutoff for significant partial correlations
<code>method.dir</code>	determines which criterion is used to select significant directions (default: prob)
<code>cutoff.dir</code>	default cutoff for significant directions
<code>verbose</code>	print information on the number of significant edges etc.

**Details**

For assessing the significance of edges in the GGM a mixture model is fitted to the partial correlations using [fdrtool](#). This results in (i) two-sided p-values for the test of non-zero correlation, (ii) corresponding posterior probabilities ( $= 1 - \text{local fdr}$ ), as well as (iii) tail area-based q-values. See Schaffer and Strimmer (2005) for details.

For determining putative directions on this GGM log-ratios of standardized partial variances are estimated, and subsequently the corresponding (local) fdr values are computed - see Opgen-Rhein and Strimmer (2007).

**Value**

`network.test.edges` returns a data frame with the following columns:

<code>pcor</code>	correlation (from <code>r.mat</code> )
<code>node1</code>	first node connected to edge

node2	second node connected to edge
pval	p-value
qval	q-value
prob	probability that edge is nonzero (= 1-local fdr)
log.spvar	log ratio of standardized partial variance (determines direction)
pval.dir	p-value (directions)
qval.dir	q-value (directions)
prob.dir	1-local fdr (directions)

Each row in the data frame corresponds to one edge, and the rows are sorted according the absolute strength of the correlation (from strongest to weakest)

extract.network processes the above data frame containing all potential edges, and returns a dataframe with a subset of edges. If applicable, an additional last column (11) contains additional information on the directionality of an edge.

```

---

z.transform

*Variance-Stabilizing Transformations of the Correlation Coefficient*

---

## Description

z.transform implements Fisher's (1921) first-order and Hotelling's (1953) second-order transformations to stabilize the distribution of the correlation coefficient. After the transformation the data follows approximately a normal distribution with constant variance (i.e. independent of the mean).

The Fisher transformation is simply  $z.transform(r) = \operatorname{atanh}(r)$ .

Hotelling's transformation requires the specification of the degree of freedom  $\kappa$  of the underlying distribution. This depends on the sample size  $n$  used to compute the sample correlation and whether simple or partial correlation coefficients are considered. If there are  $p$  variables, with  $p-2$  variables eliminated, the degree of freedom is  $\kappa = n - p + 1$ . (cf. also [dcor0](#)).

## Usage

```

z.transform(r)
hotelling.transform(r, kappa)

```

## Arguments

r	vector of sample correlations
kappa	degrees of freedom of the distribution of the correlation coefficient

## Value

The vector of transformed sample correlation coefficients.

## Author(s)
