Package 'ProFound'

December 3, 2020

Type Package

Title Photometry Tools

Version 1.14.1

Date 2020-12-03

Author Aaron Robotham

Maintainer Aaron Robotham <aaron.robotham@uwa.edu.au>

Description Core package containing all the tools for simple and advanced source extraction. This is used to create inputs for 'ProFit', or for source detection, extraction and photometry in its own right.

License LGPL-3

Depends R (>= 3.1), FITSio, magicaxis (>= 2.0.8), Rcpp (>= 1.0.2)

Imports RColorBrewer, data.table, celestial (>= 1.4.1), foreach

Suggests ProFit, knitr, rmarkdown, EBImage, imager, LaplacesDemon, Rfast, fastmatch, snow, doSNOW, bigmemory

VignetteBuilder knitr

SystemRequirements C++11

LinkingTo Rcpp

NeedsCompilation yes

R topics documented:

`ProFound-package` *Photometry Tools*

Description

Core package containing all the tools for simple and advanced source extraction. This is used to create inputs for 'ProFit', or for source detection, extraction and photometry in its own right.

Details

Package:	ProFound
Type:	Package
Version:	1.14.1
Date:	2020-12-03
License:	LGPL-3
Depends:	R (>= 3.1), FITSio, magicaxis (>= 2.0.8), Rcpp (>= 1.0.2)
Imports:	RColorBrewer, data.table, celestial (>= 1.4.1), foreach, doParallel, Rcpp
Suggests:	ProFit, knitr, rmarkdown, EBImage, imager, LaplacesDemon, Rfast, fastmatch, Rfits, Rwcs, snow, doSNOW, bigr

Examples

```
## Not run:
image=readFITS(system.file("extdata", 'VIKING/mystery_VIKING_Z.fits',
package="ProFound"))

profound=profoundProFound(image, skycut=1.5, magzero=30, verbose=TRUE, plot=TRUE)

## End(Not run)
```

FPtest *False Positive Reference Data*

Description

This data consists of 1,000 runs of a random 1000 x 1000 noise matrix through `profoundProFound`. The catalogue is a concatenation of all the segstats outputs for all of these run.

Usage

```
data("FPtest")
```

Format

A data frame with 7012 observations on the following 56 variables. See profoundProFound for a detailed discussion on each of these parameters.

segID a numeric vector

uniqueID a numeric vector

xcen a numeric vector

ycen a numeric vector

xmax a numeric vector

ymax a numeric vector

RAcen a logical vector

Deccen a logical vector

RAmax a logical vector

Decmax a logical vector

sep a numeric vector

flux a numeric vector

mag a numeric vector

cenfrac a numeric vector

N50 a numeric vector

N90 a numeric vector

N100 a numeric vector

R50 a numeric vector

R90 a numeric vector

R100 a numeric vector

SB_N50 a numeric vector

SB_N90 a numeric vector

SB_N100 a numeric vector

xsd a numeric vector

ysd a numeric vector

covxy a numeric vector

corxy a numeric vector

con a numeric vector

asymm a logical vector

flux_reflect a logical vector

mag_reflect a logical vector

semimaj a numeric vector

semimin a numeric vector

axrat a numeric vector

`ang` a numeric vector

`signif` a numeric vector

`FPlim` a numeric vector

`flux_err` a numeric vector

`mag_err` a numeric vector

`flux_err_sky` a numeric vector

`flux_err_skyRMS` a numeric vector

`flux_err_shot` a numeric vector

`sky_mean` a numeric vector

`sky_sum` a numeric vector

`skyRMS_mean` a numeric vector

`Nedge` a logical vector

`Nsky` a logical vector

`Nobject` a logical vector

`Nborder` a logical vector

`Nmask` a logical vector

`edge_frac` a logical vector

`edge_excess` a logical vector

`flag_border` a logical vector

`iter` a numeric vector

`origfrac` a numeric vector

`flag_keep` a logical vector

Details

Specifically we ran with defaults the following command 1,000 times in a loop:

profoundProFound(matrix(rnorm(1e6),1e3))

The output is then a reference of the false positive rate, since we have not injected any sources into the images. The fact we find 7,012 false detections mean we expect 7 false positives per 1e6 pixels (the size in pixels of the input matrix). To compare against any target data we need to adjust the magnitudes by the sky RMS magnitude level, i.e. add on profoundFlux2Mag(skyRMS, 0) (if the zero point is 0 for our target data). See Examples for a comparison to our included VIKING data.

Source

FPtest=

for(i in 1:1000)FPtest=rbind(FPtest,profoundProFound(matrix(rnorm(1e6),1e3))$segstats)

Examples

```
## Not run:
image=readFITS(system.file("extdata", 'VIKING/mystery_VIKING_Z.fits', package="ProFound"))
profound=profoundProFound(image, magzero=30, rotstats=TRUE)
skyRMS=median(profound$skyRMS)
magoff=profoundFlux2Mag(skyRMS, 30)
totpix=prod(profound$dim)

#We can easily compute the expected number of false positives on an image this size:
data("FPtest")
dim(FPtest)[1]*totpix/1e6/1e3

#And plot the detections and expected false positive distributions:
maghist(profound$segstats$mag, seq(-11,-1,by=0.2)+magoff)
maghist(FPtest$mag+magoff, seq(-6,-1,by=0.2)+magoff, scale=totpix/1e6/1e3, add=TRUE,
border='red')

## End(Not run)
```

`plot.fitmagpsf` *FitMagPSF diagnostic plots*

Description

A simple image / model / image - model grid.

Usage

```
## S3 method for class 'fitmagpsf'
plot(x, ...)
```

Arguments

`x`	Object of class 'fitmagpsf', as returned by `profoundFitMagPSF`.
`...`	Passed to `magimage` / `magimageWCS`

Details

Run for the side effect of generating a grid of useful diagnostic plots.

Value

Run for the side effect of generating a grid of useful diagnostic plots:

plot.profound *ProFound Diagnostic Grid*

Description

A useful visual grid of ProFound diagnostics. This is useful for checking if something very odd has occurred when running the code.

Usage

```
## S3 method for class 'profound'
plot(x, logR50 = TRUE, dmag=0.5, hist='sky', ...)
```

Arguments

x	Argument for the class dependent plot.profound function. An object of class profound as output by the profoundProFound function. This is the only structure that needs to be provided when executing plot(profound) class dependent plotting, which will use the plot.profound function.
logR50	Logical; specifies whether the bottom-centre panel uses a logarithmic y-axis for R50 (default is TRUE).
dmag	Numeric scaler; the magnitude binning scale to use (default 0.5 to reflect the axis binning). The magnitude histograms always use 0.5 magnitude bins, but this controls the y-axis scaling to give the correct normalisation as if the specified binning was used. I.e. the raw counts are scaled by an additional factor of 2 if 'dmag'=1 is specified.

hist	Character scalar; specifies the plot type for the bottom-left plot. Options are 'sky' (which is a sky pixel (image-sky)/skyRMS PDF using the objects_redo mask) or 'iters' (histogram of required iterations). Old default was 'iters', but now 'sky', since this is more useful in general.
...	Nothing to see here.

Details

Run for the side effect of generating a grid of useful diagnostic plots.

Value

Run for the side effect of generating a grid of useful diagnostic plots:

Top-left	Sky subracted image 'x$image'-'x$sky', where blue is negative, yellow is 0, and red is positive
Top-centre	Output segmentation map 'x$segim'
Top-right	Sky subracted and normalised image ('x$image'-'x$sky')/'x$skyRMS', with segment dilation extent shown in colour
Middle-left	Magnitude ('x$segstats$mag') counts histogram (max in red), scaled to counts per square degree if 'x$header' is present
Middle-centre	Output 'x$sky', where blue is negative, yellow is 0, and red is positive
Middle-right	Output 'x$skyRMS', where dark is lower values and white larger values
Bottom-left	Sky pixel ('x$image'-'x$sky')/'x$skyRMS' PDF, or dilation iteration ('x$segstats$iter') histogram (depends on 'hist')
Bottom-centre	Output mag ('x$segstats$mag') versus R50 ('x$segstats$R50')
Bottom-right	Output mag ('x$segstats$mag') versus axrat ('x$segstats$axrat')

ProFound *ProFound Source Detection*

Description

This is the highest level source detection function provided in ProFit, calculating both the initial segmentation map and reasonable estimates for the total flux apertures for each source in an automatic manner.

Usage

```
profoundProFound(image = NULL, segim = NULL, objects = NULL, mask = NULL,  skycut = 1,
pixcut = 3, tolerance = 4, ext = 2, reltol = 0, cliptol = Inf, sigma = 1, smooth = TRUE,
SBlim, SBdilate = NULL, SBN100 = 100, size = 5, shape = "disc", iters = 6,
threshold = 1.05, magzero = 0, gain = NULL, pixscale = 1, sky = NULL, skyRMS = NULL,
redosegim = FALSE, redosky = TRUE, redoskysize = 21, box = c(100,100), grid = box,
skygrid_type = 'new', type = "bicubic", skytype = "median", skyRMStype = "quanlo",
roughpedestal = FALSE, sigmasel = 1, skypixmin = prod(box)/2, boxadd = box/2,
boxiters = 0, conviters = 100, iterskyloc = TRUE, deblend = FALSE, df = 3, radtrunc = 2,
iterative = FALSE, doclip = TRUE, shiftloc = FALSE, paddim = TRUE, header,
verbose = FALSE, plot = FALSE, stats = TRUE, rotstats = FALSE, boundstats = FALSE,
nearstats = boundstats, groupstats = boundstats, group = NULL, groupby = 'segim_orig',
offset = 1, haralickstats = FALSE, sortcol = "segID", decreasing = FALSE,
lowmemory = FALSE, keepim = TRUE, watershed = 'ProFound', pixelcov = FALSE,
deblendtype = 'fit', psf = NULL, fluxweight = 'sum', convtype = 'brute',
convmode = 'extended', fluxtype = 'Raw', app_diam = 1, Ndeblendlim = Inf, ...)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. If 'image' is a list as created by readFITS, read.fits of magcutoutWCS then the image part of these lists is passed to 'image' and the correct header part is passed to 'header'. Note, image NAs are treated as masked pixels.
segim	Integer matrix; a specified segmentation map of the image. This matrix *must* be the same dimensions as 'image' if supplied. If this option is used then profoundProFound will not compute its initial segmentation map using profoundMakeSegim, which is then dilated. Instead it will use the one passed through 'segim'.
objects	Boolean matrix (1,0); optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as 'image'. If provided then this is used to initially mask pixels for determining the correct 'sky' when 'sky'=NULL.
mask	Boolean matrix or integer scalar (1,0); optional, parts of the image to mask out (i.e. ignore). If a matrix is provided, this matrix *must* be the same dimensions as 'image' where 1 means mask out and 0 means use for analysis. if a scalar is provided it indicates the exact 'image' values that should be treated as masked (e.g. by setting masked pixels to 0 or -999). The latter achieves the same effect

as setting masked 'image' pixels to NA, but allows for the fact not all programs can produce R legal NA values.

skycut — Numeric scalar; the lowest threshold to make on the 'image' in units of the skyRMS. Passed to profoundMakeSegim.

pixcut — Integer scalar; the number of pixels required to identify an object. Passed to profoundMakeSegim.

tolerance — Numeric scalar; the minimum height of the object in the units of skyRMS between its highest point (seed) and the point where it contacts another object (checked for every contact pixel). If the height is smaller than the tolerance, the object will be combined with one of its neighbours, which is the highest. The range 1-5 offers decent results usually. Passed to profoundMakeSegim.

ext — Numeric scalar; radius of the neighbourhood in pixels for the detection of neighbouring objects. Higher value smooths out small objects. Passed to profoundMakeSegim.

reltol — Numeric scalar; only relevant for 'watershed'='ProFound'. A modifier to the 'tolerance', modifying it by the ratio of the segment peak flux divided by the saddle point flux to the power 'reltol'. The default means the 'reltol' has no effect since this modifier becomes 1. A larger value of 'reltol' means segments are more aggressively merged together. Can be (and often should be in practice) negative. The effect of using 'reltol' and setting to negative is that the central brighter parts of galaxies are kept together in a single segment, and deblending is more common on the outskirts (where it should have less effect on the overall flux). The principle is that we need to be very confident a bright source needs to be split near its peak flux, but can be more aggressive in the outskirts.

cliptol — Numeric scalar; only relevant for 'watershed'='ProFound'. If ('image'-'sky')/'skyRMS' is above this level where segments touch then they are always merged, regardless of other criteria. When thinking in terms of sky RMS, values between 20-100 are probably appropriate for merging very bright parts of stars back together in optical data.

sigma — Numeric scalar; standard deviation of the blur used when 'smooth'=TRUE. Passed to profoundMakeSegim.

smooth — Logical; should smoothing be done on the target 'image'? Passed to profoundMakeSegim. If present, this will use the imblur function from the imager package. Otherwise it will use the gblur function from the EBImage package with a warning. These functions are very similar in output, but not strictly identical.

SBlim — Numeric scalar; the mag/asec^2 surface brightness threshold to apply. This is always used in conjunction with 'skycut', so set 'skycut' to be very large (e.g. Inf) if you want a pure surface brightness threshold for the segmentation. 'magzero' and 'pixscale' must also be present for this to be used. If a matrix is provided, this matrix *must* be the same dimensions as 'image'. Passed to profoundMakeSegim. If set to 'get' then the output 'SBlim' is calculated from the 'skyRMS' and 'magzero' automatically.

SBdilate — Numeric scalar; how many surface brightness mags beyond the sky RMS to push the dilation process. Default is NULL, meaning this is not triggered. The extra dilation logic is that if the new mean surface brightness in the dilated annulus is above the sky surface brightness + 'SBdilate' and we are adding more than 'SBN100' pixels then we will continue to dilate. This works well to capture

extra flux in very large extended structures, where the fractional flux might not be changing much, but where we can safely keep dilating. Sensible values are between 0-2 (i.e. with 100 pixels we might be able to reliably push 2 mags fainter than the nominal sky surface brightness).

`SBN100` Integer scalar; the number of new annulus pixels in our dilated segment required to trigger the '`SBdilate`' criteria.

`size` Integer scalar; the size (e.g. width/diameter) of the dilation kernel in pixels. Should be an odd number else will be rounded up to the nearest odd number. See `makeBrush`. Passed to `profoundMakeSegimDilate`.

`shape` Character scalar; the shape of the dilation kernel. See `makeBrush`. Passed to `profoundMakeSegimDilate`.

`iters` Integer scalar; the maximum number of curve of growth dilations that should be made. This needs to be large enough to capture all the flux for sources of interest, but increasing this will increase the computation time for `profoundProFound`. If this is set to 0 then the undilated '`segim`' image, whether provided or computed internally via `profoundMakeSegim`, will be used instead.

`threshold` Numeric scalar; After the curve of growth dilations, '`threshold`' is the relative change of the converging property (see '`converge`') that flags convergence. If consecutive iterations have a relative difference within this ratio then the dilation is stopped, and this iteration is used to define the segmentation of the object. The effect of this is that different objects will be dilated for a different number of iterations. Usually fainter sources require more. Note from v1.4: covergence has to be monotonically decreasing as dilation occurs, i.e. the flux can grow from x1.4 to x1.1 (next iteration), but not x1.4 to x2. Dilations with increasing growth rate are ignored.

`magzero` Numeric scalar; the magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega). If provided along with '`pixscale`' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.

`gain` Numeric scalar; the gain (in photo-electrons per ADU). This is only used to compute object shot-noise component of the flux error (else this is set to 0).

`pixscale` Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1 (default), then the output is in terms of pixels, otherwise it is in arcseconds. If provided along with '`magzero`' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.

`sky` User provided estimate of the absolute sky level. If this is not provided then it will be computed internally using `profoundMakeSkyGrid`. Can be a scalar or a matrix matching the dimensions of '`image`' (allows values to vary per pixel). This will be subtracted off the '`image`' internally, so only provide this if the sky does need to be subtracted!

`skyRMS` User provided estimate of the RMS of the sky. If this is not provided then it will be computed internally using `profoundMakeSkyGrid`. Can be a scalar or a matrix matching the dimensions of '`image`' (allows values to vary per pixel).

`redosegim` Logical; should the segmentation map be modified based using the interim "better sky"? This means pixels falling below the new '`skycut`' would be excluded from the final segmentation map. This is usually only required if the sky subtraction was radically poor and complex in the first place. Will be forced to

FALSE if the user supplies a segmentation map. If the user wants to flag object pixels they should pass it to 'objects'.

redosky — Logical; should the sky and sky RMS grids be re-computed using the final segmentation map? This uses profoundMakeSkyGrid to compute the sky and sky RMS grids. If 'redosky'=TRUE then the output will include the aggressively masked 'objects_redo' image, if 'redosky'=FALSE then 'objects_redo' will be NA.

redoskysize — Integer scalar; the size (e.g. width/diameter) of the dilation kernel in pixels to apply to the 'object' mask before performing the initial and final aggressively masked sky estimates (the latter is only relevant if 'redosky'=TRUE). Should be an odd number else will be rounded up to the nearest odd number. See makeBrush. Dilation is done by profoundMakeSegimDilate. If 'redosky'=TRUE, the final dilated 'objects' mask is returned as 'objects_redo'. As a rule of thumb you probably want ~50% of your image pixels to be masked as objects, much more than this and you might not be able to sample enough sky pixels, much more less and the sky estimates might be biased by object flux in the wings.

box — Integer vector; the dimensions of the box car filter to estimate the sky with. For convenience, if length 1 then both dimensions of 'box' used internally are assumed to equal the specified 'box'. I.e. 200 would be interpreted as c(200,200). Dependent default arguments ('grid', 'boxadd' and 'skypixmin') are updated sensibly.

grid — Integer vector; the resolution of the background grid to estimate the sky with. By default this is set to be the same as the 'box'.

skygrid_type — Character scalar; either 'new' (the new ADACS C++ sky grid code) or 'old' (the older R based code as used for ProFound <= v1.10).

type — Character scalar; either "bilinear" for bilinear interpolation or "bicubic" for bicubic interpolation. The former creates sharper edges, the later is guaranteed to be first order differentiable. As of ProFound v1.13.0 we use the IntpAkimaUniform2 version available from www.geometrictools.com under a Boost 1.0 license (replacing the older Akima package and ADACS implementations, the former being memory intensive and the latter caused some small numerical artefacts).

skytype — Character scalar; the type of sky level estimator used. Allowed options are 'median' (the default), 'mean', 'mode' and 'converge' (see profoundSkyEstLoc for an explanation of what these estimators do). In all cases this is the estimator applied to unmasked and non-object pixels. If 'doclip'=TRUE then the pixels will be dynamically sigma clipped before the estimator is run.

skyRMStype — Character scalar; the type of sky level estimator used. Allowed options are 'quanlo' (the default), 'quanhi', 'quanboth', 'sd' and 'converge' (see profoundSkyEstLoc for an explanation of what these estimators do). In all cases this is the estimator applied to unmasked and non-object pixels. If 'doclip'=TRUE then the pixels will be dynamically sigma clipped before the estimator is run.

roughpedestal — Logical; when the initial "rough sky" is computed, should only a pedestal (based on the median of the sky map) be used for the sky? This is a good option if the image is known to contain a *very* large (many times the 'box' size) galaxy that might otherwise be over subtracted by the initial rough sky map.

`sigmasel` Numeric scalar; the quantile to use when trying to estimate the true standard-deviation of the sky distribution. If contamination is low then the default of 1 is about optimal in terms of S/N, but you might need to make the value lower when contamination is very high.

`skypixmin` Numeric scalar; the minimum number of sky pixels desired in our cutout. The default is that we need half the original number of pixels in the 'box' to be sky.

`boxadd` Integer vector; the dimensions to add to the 'box' to capture more pixels if 'skypixmin' has not been achieved. By default this is set to be the same as the 'box'/2.

`boxiters` Integer scalar; the number of 'box'+'boxadd' iterations to attempt in order to capture 'skypixmin' sky pixels. The default means the box will not be grown at all.

`conviters` Integer scalar; number of iterative sky convergence steps when 'skytype' = 'converge' and/or 'skyRMStype' = 'converge'.

`iterskyloc` Logical; should the last segment dilation be used to estimate a local sky value? If this is TRUE then this estimate is used to determine flux convergence for the dilations. It will also be used to return the additional 'skyseg_mean' column in the segstats output provided. If TRUE then one additional dilation is made compared to the specified 'iters'.

`deblend` Logical; should segment flux be deblended using `profoundFluxDeblend` and these columns appended to the end of the output 'segstats'?

`df` Integer scalar; degrees of freedom for the non-parametric spline fitting. Only relevant if 'deblend'=TRUE, see `profoundFluxDeblend`.

`radtrunc` Numeric scalar; the maximum allowed radius beyond the edge-most segment pixel to consider when deblending. Keeping this low (1-3) ensures segments do not gather flux from very distant regions of the group. Only relevant if 'deblend'=TRUE, see `profoundFluxDeblend`.

`iterative` Logical; should each segment profile fit be subtracted as it goes along? TRUE tends to remove the pedestal from a large galaxy that has faint objects embedded on top. Only relevant if 'deblend'=TRUE, see `profoundFluxDeblend`.

`doclip` Logical; should the unmasked non-object pixels used to estimate to local sky value be further sigma-clipped using `magclip`? Whether this is used or not is a product of the quality of the objects extraction. If all detectable objects really have been found and the dilated objects mask leaves only apparent sky pixels then an advanced user might be confident enough to set this to FALSE. If in doubt, leave as TRUE.

`shiftloc` Logical; should the cutout centre for the sky shift from 'loc' of the desired 'box' size extends beyond the edge of the image? (See `magcutout` for details).

`paddim` Logical; should the cutout be padded with image data until it meets the desired 'box' size (if 'shiftloc' is true) or padded with NAs for data outside the image boundary otherwise? (See `magcutout` for details).

`header` Full FITS header in table or vector format. If this is provided then the segmentations statistics table will gain 'RAcen' and 'Decen' coordinate outputs. Legal table format headers are provided by the `read.fitshdr` function or the 'hdr' list output of `read.fits` in the astro package; the 'hdr' output of `readFITS` in

the FITSio package or the 'header' output of magcutoutWCS. Missing header keywords are printed out and other header option arguments are used in these cases. See magWCSxy2radec.

verbose — Logical; should verbose output be displayed to the user? Since a big 'image' can take a long time to run, you might want to monitor progress.

plot — Logical; should a diagnostic plot be generated? This is useful when you only have a small number of sources (roughly a few hundred). With more than this it can start to take a long time to make the plot!

stats — Logical; should statistics on the segmented objects be returned using profoundSegimStats? If 'magzero' and 'pixscale' have been provided then some of the outputs are computed in terms of magnitude and mag/asec^2 rather than flux and flux/pix^2 (see Value).

rotstats — Logical; if TRUE then the 'asymm', 'flux_reflect' and 'mag_reflect' are computed, else they are set to NA. This is because they are very expensive to compute compared to other photometric properties.

boundstats — Logical; if TRUE then various pixel boundary statistics are computed ('Nedge', 'Nsky', 'Nobject', 'Nborder', 'edge_frac', 'edge_excess' and 'FlagBorder'). If FALSE these return NA instead (saving computation time). Note by construction 'Nedge' = 'Nobject' + 'Nsky' + 'Nborder'. If you want to adjust specifically for 'Nmask' then 'Nsky' = 'Nsky' - 'Nmask'.

nearstats — Logical; if TRUE then the IDs of nearby segments is calculated via profoundSegimNear and output to the returned object 'near'. By default this option is linked to 'boundstats', i.e. it is assumed if you want boundary statistics then you probably also want nearby object IDs returned.

groupstats — Logical; if TRUE then the IDs of grouped dilated segments (based on the output 'segim') is calculated via profoundSegimGroup and output to the list object 'group'. By default this option is linked to 'boundstats', i.e. it is assumed if you want boundary statistics then you probably also want grouped object information returned. If 'stats'=TRUE is also set then this flag will also create the 'groupstats' output of photometric properties of the groups.

group — List; you can pass in the output from profoundSegimGroup directly, meaning groups will not be re-computed internally. This might be useful for speed in certain matched photometry applications.

groupby — Character scalar; How should the grouped segmentation map be formed that will be used to produce the 'groupstats' output? Options are either via 'segim' or 'segim_orig'. 'segim' will create more groups, 'segim_orig' will have less.

offset — Integer scalar; the distance to offset when searching for nearby segments (used in both profoundSegimStats and profoundSegimNear).

haralickstats — Logical; if TRUE then the Haralick texture statistics are computed using the EBImage function computeFeatures.haralick. For more detail see the original paper: http://haralick.org/journals/TexturalFeatures.pdf, and a useful online EBImage document: http://earlglynn.github.io/RNotes/package/EBImage/Haralick-Textural-Features.html.

sortcol — Character scalar; name of the output column that the returned segmentation statistics data.frame should be sorted by (the default is segID, i.e. segment order). See below for column names and contents.

`decreasing` Logical; if FALSE (default) the segmentation statistics data.frame will be sorted in increasing order, if TRUE the data.frame will be sorted in decreasing order.

`lowmemory` Logical; if TRUE then a low memory mode of ProFound will be used. This limits the large 'image' pixel matched outputs to just 'segim', with 'segim_orig', 'objects' and 'objects_redo' set to NULL, and 'sky' and 'skyRMS' set to 0. Internally the sky and skyRMS are used as normal for flux estimates, but they are removed as soon as possible within the function in order to free up memory.

`keepim` Logical; if TRUE then the input 'image' and 'mask' matrices are passed through to the image output of the function. If FALSE then this is set to NULL.

`watershed` Character scalar; the funciton to use to achieve the watershed deblend. Allowed options are 'EBImage' for EBImage::watershed, and 'ProFound' for the new Rcpp implementation included with the ProFound package.

`pixelcov` Logical, should pixel covariance be considered when computing errors? TRUE uses profoundPixelCorrelation and the 'cor_err_func' output which is then passed into profoundSegimStats. You can also directly pass it the 'cor_err_func' function that you have already computed for the type of data being used. This means you do not need to recompute the correlation function for every 'image' (which would be quite slow).

`deblendtype` Character scalar, either 'fit' (default, where the segments in the image are approximately fitted for deblending) or 'psf' (where a PSF must be provided to argument 'psf'). Only relevant if 'deblend'=TRUE, see profoundFluxDeblend.

`psf` Numeric matrix; must be provided if 'deblendtype'='psf'. Only relevant if 'deblend'=TRUE, see profoundFluxDeblend.

`fluxweight` Numeric scalar; only relevent when 'deblendtype'='psf'. Either 'sum' (where the sum of the current segment weights the deblend solution), 'peak' (where only the peak pixel flux in the segment it used) or 'none' (no additional weighting is used). Only relevant if 'deblend'=TRUE, see profoundFluxDeblend.

`convtype` Character scalar, only relevent when 'deblendtype'='psf'. Specifies the type on convolver to use. Available options are displayed by running profitAvailableConvolvers, but usually one of 'brute' or 'fftw'. The latter tends to be fastest when the supplied 'psf' is much smaller than the 'image' (factor greater than 4 in each dimension). As the sizes become comparable, fftw becomes faster since it scales better with the product of 'psf' and 'image' pixels.

`convmode` Character scalar, only relevent when 'deblendtype'='psf'. Either 'extended' (the whole segment is convolved with the target PSF when determining the deblend) or 'psf' (the provided PSF is centred at the peak flux for deblending). Only relevent when 'deblendtype'='psf'. The former makes more sense for well resolved images (say optical) where the main issue in the deblending is the overlapping of resolved flux components. The latter works better in the regime where the image is barely resolved beyond the PSF, and this dominates the uncertainty of the deblend.

`fluxtype` Character scaler; specifies whether fluxes will be output in Jansky / MicroJansky ('Jansky' / 'microjansky'), or in raw/unscaled image ADUs ('Raw' / 'ADU' / 'ADUs', the default). You can only use Jansky / MicroJansky if the specified 'magzero' gets the data into the AB system, else the fluxes will not be Jansky.

app_diam	Numeric scalar; the diameter in arc seconds to use for pseudo aperture photometry. This will use the appropriate pixel scale to convert the aperture into image units. The psuedo aperture photometry is output to columns 'flux_app' and 'mag_app' in 'segstats'.
Ndeblendlim	Integer scalar; the limit for the number of pixels to consider in a deblending complex (Ngroup [number of segments in the group] x Npix [number of pixels in the group]). You might want to set this to a value similar to allowable machine memory (1e8 - 1e9 often) just to avoid extreme cases (e.g. large stars with lots of pixels and lots of segments). Only relevant if 'deblend'=TRUE, see profoundFluxDeblend.
...	Further arguments to be passed to magimage. Only relevant is 'plot'=TRUE.

Details

This high level function is both a source detection and a segmented aperture growing function. The latter is achieved through consecutive dilation and flux measurement operations. It is not super fast, but it is designed to be fairly robust and fast enough for most use cases.

profoundProFound initially makes a segmentation map using the profoundMakeSegim function. It then makes repeated dilations and flux measurements of this segmentation map using profoundMakeSegimDilate, and calculates the convergent flux segment for each source. These are combined to make a final segmentation map with associated source statistics (if requested).

The defaults should work reasonably well on modern survey data (see Examples), but should the solution not be ideal try modifying these parameters (in order of impact priority): 'skycut', 'pixcut', 'tolerance', 'sigma', 'ext'.

profoundMakeSegimDilate is similar in nature to the pixel growing objmask routine in IRAF (see the 'ngrow' and 'agrow' description at http://iraf.noao.edu/projects/ccdmosaic/objmasks/objmasks.html). This similarity was discovered after implementation, but it is worth noting that the higher level curve of growth function profoundProFound is not trivially replicated by other astronomy tools.

Value

An object list of class 'profound' containing:

segim	Integer matrix; the dilated and converged segmentation map matched pixel by pixel to 'image'.
segim_orig	Integer matrix; the pre-dilated segmentation map matched pixel by pixel to 'image'.
objects	Logical matrix; the object map matched pixel by pixel to 'image'. 1 means there is an object at this pixel, 0 means it is a sky pixel. Can be used as a mask in various other functions that require objects to be masked out.
objects_redo	Logical matrix; the dilated object map matched pixel by pixel to 'image'. See 'redosky' and 'redoskysize'. Can be used as a mask in various other functions that require objects to be masked out.
sky	The estimated sky level of the 'image'.
skyRMS	The estimated sky RMS of the 'image'.

image	The input 'image' matrix if 'keepim'=TRUE, else NULL.
mask	The input or computed 'mask' matrix if 'keepim'=TRUE, else NULL.
segstats	If 'stats'=TRUE then contains the output of profoundSegimStats run using the final 'segim' (see below), otherwise NULL.
Nseg	The total number of segments extracted (dim(segstats)[1]).
near	If 'nearstats'=TRUE then contains the output of profoundSegimNear.
group	If 'groupstats'=TRUE then contains the output of profoundSegimGroup.
groupstats	If 'groupstats'=TRUE and 'stats'=TRUE then contains the output of profoundSegimStats run using the final 'group$groupim' (see below), otherwise NULL.
header	The header provided, if missing this is NULL.
SBlim	The surface brightness limit of detected objects. Requires at least 'magzero' to be provided and 'skycut'>0, else NULL.
magzero	The assumed magnitude zero point. This is relevant to various outputs returned by the segmentation statistics.
dim	The dimensions of the processed image.
pixscale	The assumed pixel scale. This is relevant to various outputs returned by the segmentation statistics.
gain	The assumed image gain (if NULL it was not used). This is relevant to various outputs returned by the segmentation statistics.
imarea	The area of the provided image in degrees squared.
skyLL	The log-likelihood of negative sky pixel Chi-Sq distribution (the larger the better the sky estimation).
call	The original function call.
date	The date, more specifically the output of date.
time	The elapsed run time in seconds.
ProFound.version	The version of ProFound run, more specifically the output of packageVersion('ProFound').
R.version	The version of R run, more specifically the output of R.version.

If 'stats'=TRUE then the function profoundSegimStats is called and the 'segstats' part of the returned list will contain a data.frame with columns (else NULL):

segID	Segmentation ID, which can be matched against values in 'segim'
uniqueID	Unique ID, which is fairly static and based on the xmax and ymax position
xcen	Flux weighted x centre
ycen	Flux weighted y centre
xmax	x position of maximum flux
ymax	y position of maximum flux
RAcen	Flux weighted degrees Right Ascension centre (only present if a 'header' is provided)

Deccen	Flux weighted degrees Declination centre (only present if a 'header' is provided)
RAmax	Right Ascension of maximum flux (only present if a 'header' is provided)
Decmax	Declination of maximum flux (only present if a 'header' is provided)
sep	Radial offset between the cen and max definition of the centre (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
flux	Total flux (calculated using 'image'-'sky') in ADUs or Jansky
mag	Total flux converted to mag using 'magzero'
flux_app	Pseudo aperture (as specified by 'app_rad') flux (calculated using 'image'-'sky') in ADUs or Jansky
mag_app	Pseudo aperture (as specified by 'app_rad') flux converted to mag using 'magzero'
cenfrac	Fraction of flux in the brightest pixel
N50	Number of brightest pixels containing 50% of the flux
N90	Number of brightest pixels containing 90% of the flux
N100	Total number of pixels in this segment, i.e. contains 100% of the flux
R50	Approximate elliptical semi-major axis containing 50% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
R90	Approximate elliptical semi-major axis containing 90% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
R100	Approximate elliptical semi-major axis containing 100% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
SB_N50	Mean surface brightness containing brightest 50% of the flux, calculated as 'flux'*0.5/'N50' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
SB_N90	Mean surface brightness containing brightest 90% of the flux, calculated as 'flux'*0.9/'N90' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
SB_N100	Mean surface brightness containing all of the flux, calculated as 'flux'/'N100' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
xsd	Weighted standard deviation in x (always in units of pix)
ysd	Weighted standard deviation in y (always in units of pix)
covxy	Weighted covariance in xy (always in units of pix)
corxy	Weighted correlation in xy (always in units of pix)
con	Concentration, 'R50'/'R90'
asymm	180 degree flux asymmetry (0-1, where 0 is perfect symmetry and 1 complete asymmetry)
flux_reflect	Flux corrected for asymmetry by doubling the contribution of flux for asymmetric pixels (defined as no matching segment pixel found when the segment is rotated through 180 degrees)
mag_reflect	'flux_reflect' converted to mag using 'magzero'

semimaj	Weighted standard deviation along the major axis, i.e. the semi-major first moment, so ~2 times this would be a typical major axis Kron radius (always in units of pix)
semimin	Weighted standard deviation along the minor axis, i.e. the semi-minor first moment, so ~2 times this would be a typical minor axis Kron radius (always in units of pix)
axrat	Axial ratio as given by min/maj
ang	Orientation of the semi-major axis in degrees. This has the convention that 0= | (vertical), 45= \, 90= - (horizontal), 135= /, 180= | (vertical)
signif	Approximate singificance of the detection using the Chi-Square distribution
FPlim	Approximate false-positive significance limit below which one such source might appear spuriously on an image this large
flux_err	Estimated total error in the flux for the segment
mag_err	Estimated total error in the magnitude for the segment
flux_err_sky	Sky subtraction component of the flux error
flux_err_skyRMS	Sky RMS component of the flux error
flux_err_shot	Object shot-noise component of the flux error (only if 'gain' is provided)
flux_err_cor	Error component due to pixel correlation
sky_mean	Mean flux of the sky over all segment pixels
sky_sum	Total flux of the sky over all segment pixels
skyRMS_mean	Mean value of the sky RMS over all segment pixels
Nedge	Number of edge segment pixels that make up the outer edge of the segment
Nsky	Number of edge segment pixels that are touching sky
Nobject	Number of edge segment pixels that are touching another object segment
Nborder	Number of edge segment pixels that are touching the 'image' border
Nmask	Number of edge segment pixels that are touching a masked pixel (note NAs in 'image' are also treated as masked pixels)
edge_frac	Fraction of edge segment pixels that are touching the sky i.e. 'Nsky'/'Nedge', higher generally meaning more robust segmentation statistics
edge_excess	Ratio of the number of edge pixels to the expected number given the elliptical geometry measurements of the segment. If this is larger than 1 then it is a sign that the segment geometry is irregular, and is likely a flag for compromised photometry
flag_border	A binary flag telling the user which 'image' borders the segment touches. The bottom of the 'image' is flagged 1, left=2, top=4 and right=8. A summed combination of these flags indicate the segment is in a corner touching two borders: bottom-left=3, top-left=6, top-right=12, bottom-right=9.
iter	The iteration number when the source was flagged as having convergent flux
origfrac	The ratio between the final converged flux and the initial profoundMakeSegim iso-contour estimate

Norig	Number of pixels in the non-dilated (i.e. original) segment. This will be >= 'pixcut' by construction.
skyseg_mean	This only has a value if 'iterskyloc'=TRUE (otherwise NA). If provided it represents the mean sky for the outer dilation annulus created when dilating, i.e. a very local estimate of the sky. To use it the fluxes and mags provided need to have the current sky ('sky_sum') added back on and the new sky ('skyseg_mean' x 'N100') subtracted.
flag_keep	A suggested flag for selecting good objects. Objects flagged FALSE have hit the iteration limit and have grown their flux by more than the median for all objects at the iteration limit. This tends to suggest a problem with the sky in the location of the segment.

`profoundCatMerge` *Catalogue Merging Tool*

Description

Merges segmentation and grouped segmentation catalogues based on which groups are preferred.

Usage

```
profoundCatMerge(segstats = NULL, groupstats = NULL, groupsegID = NULL,
groupID_merge = NULL, flag = TRUE, rowreset = FALSE)
```

Arguments

`segstats`	Data.frame, segmentation catalogue output from '`profoundProFound`'.
`groupstats`	Data.frame, grouped segmentation catalogue output from '`profoundProFound`'.
`groupsegID`	List; group information as output by '`profoundSegimGroup`' or '`profoundProFound`'. Must correspond to the supplied '`segstats`' and '`groupstats`'.
`groupID_merge`	Integer vector; group IDs that are preferred solutions. All segmented belonging to the corresponding group will be removed, and the new group photometry inserted instead.
`flag`	Logical; should an extra column be added to the end specifying the origin of the photometry (either 'seg' for the segmentation map, or 'group' for the grouped segmentation map)?
`rowreset`	Logical; should the data.frame row names be reset to be 1:Nrow of the data.frame? The default leaves a trace of the group segment selection (i.e. you can see the selected row numbers from the provided '`segstats`').

Details

Handy tool to robustly merge catalogues based on preferred solutions.

Value

Merged catalogue. This will have the same number of columns as '`segstats`', with an additional column at the end called 'origin' that flags whether the object came from the segmentation catalogue (seg) or grouped segmentation catalogue (group).

---

profoundChisel *Noise Chisel Esque Sky*

Description

This is an implementation of a Noise Chisel like approach method of identifying sky pixels. It is conceptually similar on some regards, but does not attempt to produce the same solutions (i.e. it is more like "inspired by").

Usage

```
profoundChisel(image = NULL, sky = NULL, skythresh = 0.005, blurcut = 0.01,
objthresh = 1 - skythresh, sigma = 2, iterchisel = 5, itersky = 5,
objbias = 0.5, box = 100, skyconv = 0.01)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
sky	User provided estimate of the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!
skythresh	Numeric scalar; the quantile level to use to identify sink pixels for the sky (so should be between 0 and 1).

blurcut	Numeric scalar; PDF level to cut the blurring kernel at when dilating. Lower values mean larger dilations.
objthresh	Numeric scalar; the quantile level to use to identify source pixels for real objects (so should be between 0 and 1).
sigma	Numeric scalar; standard deviation of the blur used. This should be well matched to the PSF of the image in most cases.
iterchisel	Integer scalar; how many iterations of the inner chisel routine to run for.
itersky	Integer scalar; how many iterations of the outer sky estimation routine to run for.
objbias	Numeric scalar; how much to bias the dilations towards assuming pixels belong to objects (larger values mean more object pixels will in general be created).
box	Integer scalar; the dimensions of the box car filter to estimate the sky with.
skyconv	Numeric scalar; when <= 'skyconv' fraction of pixels change sky/object designation, the solution is considered converged and 'itersky' iterations stop.

Details

This is an implementation of a Noise Chisel like approach method of identifying sky pixels. It is conceptually similar on some regards, but does not attempt to produce the same solutions (i.e. it is more like "inspired by").

Value

A list with two parts:

objects	Logical matrix; the object map matched pixel by pixel to 'image'. 1 means there is an object at this pixel, 0 means it is a sky pixel. Can be used as a mask in various other functions that require objects to be masked out.
sky	The estimated sky level of the 'image'.

`profoundDrawEllipse` *Draw Ellipse*

Description

Draws multiple ellipses on a plot window.

Usage

```
profoundDrawEllipse(xcen = 0, ycen = 0, rad = 1, axrat = 1, ang = 0, box = 0, ...)
```

Arguments

`xcen`	Numeric vector; x centre/s of the ellipse/s.
`ycen`	Numeric vector; y centre/s of the ellipse/s.
`rad`	Numeric vector; the major axis extent of the ellipse/s.
`axrat`	Numeric vector; the axial ratio of the ellipse/s as given by '`radlo`'/'`radhi`'.
`ang`	Numeric vector; the angle of the ellipse/s in the usual ProFit sense, see `profitMakeModel`.
`box`	Numeric vector; the boxiness of the ellipse/s in the usual ProFit sense, see `profitMakeModel`.
`...`	Further arguments to be passed to `lines` to draw the ellipse/s.

Details

This function uses all the standard `ProFit` conventions to define the input parameters

Value

No value is returned, this function is run purely for the side effect of drawing an ellipse.

profoundFitMagPSF *Fit PSF Magnitudes to an Image*

Description

Fits PSF mags to an image with known source positions. This is the best deblend option in the regime where the sources are not well resolved, but the source positions are reasonably well defined.

Usage

```
profoundFitMagPSF(xcen = NULL, ycen = NULL, RAcen = NULL, Deccen = NULL, mag = NULL,
image = NULL, im_sigma = NULL, mask = NULL, psf = NULL, fit_iters = 5, magdiff = 1,
modxy = FALSE, sigthresh = 0, itersub = TRUE, magzero = 0, modelout = TRUE,
fluxtype = 'Raw', psf_redosky = FALSE, fluxext = FALSE, header = NULL, doProFound = FALSE,
findextra = FALSE, verbose = FALSE, ...)
```

Arguments

xcen	Numeric vector; x centres. If provided, must be the same length as 'mag', and be paired with 'ycen'.
ycen	Numeric vector; y centres. If provided, must be the same length as 'mag', and be paired with 'xcen'.
RAcen	Numeric vector; right ascension centres in degrees. If provided, must be the same length as 'mag', and be paired with 'Deccen'.
Deccen	Numeric vector; declination centres in degrees. If provided, must be the same length as 'mag', and be paired with 'RAcen'.
mag	Numeric vector; required, initial PSF mags. This is what will be fitted.
image	Numeric matrix; required, the image we want to analyse. If 'image' is a list as created by readFITS, read.fits of magcutoutWCS then the image part of these lists is passed to 'image' and the correct header part is passed to 'header'. Note, image NAs are treated as masked pixels.
im_sigma	Numeric matrix; required, the measurement errors per pixel (expressed in terms of sigma).
mask	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
psf	Numeric matrix; required, an empirical point spread function (PSF) image matrix that ProFit will use to convolve the model.
fit_iters	Integer scalar; how many iterations should be run? Usually converges quite quickly, so rarely needs to be much larger than 5 (default).

`magdiff` Numeric scalar; required, what is the allowed magnitude adjustment per iteration. Smaller values means faster fitting, but the correct solution obviously needs to lie with 'iters'x'magdiff' for all PSF magnitudes.

`modxy` Logical; should 'xcen' and 'ycen' positions be adjusted during fitting? This adds computation time (roughly an extra 50%), but generally produces slightly better fits. It is limited so positions can only move 0.5 pixels per iteration, so the maximum move possible is 'iters' x 0.5 pixels.

`sigthresh` Numeric scalar; the cut level to apply before re-estimating the 'xcen' and 'ycen' positions. Higher means only brighter pixels are considered so is more robust, but it means fainter sources might not be adjusted at all. Only relevant if 'modxy'=TRUE.

`itersub` Logical; should each marginalised source profile be subtracted as we loop around the sources within a given iteration? The reason to perhaps set this to FALSE is that the source order will then affect the results (the earlier source will collect more flux where they overlap), but the overall solution will always be better with this set to TRUE (default).

`magzero` Numeric scalar; the magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega).

`modelout` Logical; should the full model image be output?

`fluxtype` Character scaler; specifies whether fluxes will be output in Jansky / MicroJansky ('Jansky' / 'microjansky'), or in raw/unscaled image ADUs ('Raw' / 'ADU' / 'ADUs', the default). You can only use 'Jansky' if the specified 'magzero' gets the data into the AB system, else the fluxes will not be Jansky.

`psf_redosky` Logical; should the sky calulcated by `profoundProFound` be subtracted from the target image? Since FIR frames are often confused, this should be turned on with care since possibly none of the pixels are a good sky reference. Put another way, you really need to trust your PSF wings.

`fluxext` Logical; should the full model be used to compute an image deblending function better suited for extended sources? This means fluxes are guaranteed to add up to those available in the 'image'. The fit PSF can differ, especially if the 'psf' supplied is not in detail identical to the true 'image' PSF. In practice we find that using 'fluxext'=FALSE works better when the sources are not well resolved (assuming the true 'psf' ~ true PSF), but when sources are marginally extended then 'fluxext'=TRUE is probably the safer mode to use (hence the name).

`header` Full FITS header in table or vector format. Legal table format headers are provided by the `read.fitshdr` function or the 'hdr' list output of `read.fits` in the `astro` package; the 'hdr' output of `readFITS` in the `FITSio` package or the 'header' output of `magcutoutWCS`. If a header is provided then key words will be taken from here as a priority. Missing header keywords are printed out and other header option arguments are used in these cases.

`doProFound` Logical; if TRUE then `profoundProFound` will be run with the arguments provided by .... This will be used to determine 'xcen', 'ycen' and 'mag' blindly.

`findextra` Logical; if TRUE then after an initial run of `profoundFitMagPSF` `profoundProFound` is used to find additional sources that cannot be well modelled. The combined set if the initial sources and the new extra sources are then passed back

	into profoundFitMagPSF for a final run. The main source list is output to 'psfstats', and the extra sources are output to 'psfstats_extra'. 'psfstats_extra' is otherwise NULL.
verbose	Logical; should verbose output be displayed to the user? Since a big 'image' can take a long time to run, you might want to monitor progress.
...	Arguments to be passed on to profoundProFound. Only relevant if 'doProFound'=TRUE or 'findextra'=TRUE.

Details

This function uses ProFit to make a full model image. It then makes a model image for each indiviual PSF component and optimises just this alone. This means a maximum likelihood solution is converged on very efficiently, and is inspired by Expectation Maximisation which is often used for mixture model problems (which this basically is) for the reason of fast convergence. Here we use optim with 'method' Brent to achieve the individual PSF optimisations.

Value

Object of class "fitmagpsf", a list containing:

psfstats	Data.frame; main source photometric properties (see below).
origmodel	Numeric matric; the original model image before optimisation. This will have the same dimensions as the input 'image'. Only relevant if 'modelout'=TRUE, else NA.
finalmodel	Numeric matric; the final model image after optimisation. This will have the same dimensions as the input 'image'. Only relevant if 'modelout'=TRUE, else NA.
origLL	Numeric scalar; the original data-model log-likelihood. Only relevant if 'modelout'=TRUE, else NA.
finalLL	Numeric scalar; the final data-model log-likelihood. Only relevant if 'modelout'=TRUE, else NA.
image	Numeric matric; the image directly used for fitting. This might have an additional sky component removed (if 'doProFound'=TRUE) and NAs for masked regions.
header	The header provided, if missing this is NULL.
psfstats_extra	Data.frame; xtra photometric properties if 'findextra'=TRUE, otherwise NULL (see below).
profound	List; an object of class profound as output by the profoundProFound function. This contains the output for the ProFound part of the analysis if 'doProFound'=TRUE or 'findextra'=TRUE.
mask	The input or computed 'mask' matrix, else NULL.
call	The original function call.
date	The date, more specifically the output of date.
time	The elapsed run time in seconds.

`ProFound.version`
: The version of `ProFound` run, more specifically the output of `packageVersion`('ProFound').

`R.version`
: The version of `R` run, more specifically the output of `R.version`.

'`psfstats`' '`psfstats_extra`' data.frames have the following columns:

`xcen`
: Numeric vector; x centres. If '`modxy`'=FALSE these will be the same as the input '`xcen`', but if '`modxy`'=TRUE they will be adjusted.

`ycen`
: Numeric vector; y centres. If '`modxy`'=FALSE these will be the same as the input '`ycen`', but if '`modxy`'=TRUE they will be adjusted.

`flux`
: Numeric vector; the final fitted PSF fluxes (either Jansky or raw, depending on '`fluxtype`'). This will be the same length as the input '`mag`' vector.

`flux_err`
: Numeric vector; the final fitted PSF flux errors (either Jansky or raw, depending on '`fluxtype`'). This will be the same length as the input '`mag`' vector.

`mag`
: Numeric vector; the final fitted PSF magnitudes. This will be the same length as the input '`mag`' vector.

`mag_err`
: Numeric vector; the final fitted PSF magnitude errors. This will be the same length as the input '`mag`' vector.

`psf`
: Numeric vector; the log-likelihood of the individual source fit.

`signif`
: Numeric vector; approximate singificance of the detection using the Chi-Square distribution.

```

`profoundFlux2Mag` *Convert between fluxes and magnitudes.*

Description

Simple functions to concert between magnitudes and flux given a certain magnitude zero-point.

Usage

```
profoundFlux2Mag(flux = 1, magzero = 0)
profoundMag2Flux(mag = 0, magzero = 0)
profoundFlux2SB(flux = 1, magzero = 0, pixscale = 1)
profoundSB2Flux(SB = 0, magzero = 0, pixscale = 1)
```

Arguments

flux	Numeric scalar/vector; flux in ADUs given the 'magzero'.
mag	Numeric scalar/vector; magnitude given the 'magzero'.
magzero	Numeric scalar/vector; magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega).
SB	Numeric scalar/vector; surface brightness in mag/asec^2.
pixscale	Numeric scalar/vector; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1, then the output is in terms of pixels, otherwise it is in arcseconds.

Details

These functions are here to prevent silly mistakes, but the conversion is almost trivial.

Value

profoundFlux2Mag
: Returns the magnitude, where 'mag' = -2.5 * log10('flux') + 'magzero')

profoundMag2Flux
: Returns the flux, where 'flux' = 10^(-0.4 * ('mag' - 'magzero'))

profoundFluxDeblend *Mid Level Image Deblender*

Description

Given a target image, a segmentation map, image segstats and group properties, this function will attempt a non-parametric deblend based on local fitting of B-splines to create a weight map for each segment in a group. Flux is guaranteed to be conserved, and errors are appropriately rescaled.

Usage

```
profoundFluxDeblend(image = NULL, segim = NULL, segstats = NULL, groupim = NULL,
groupsegID = NULL, sky = 0, profound = NULL, magzero = 0,  df = 3, radtrunc = 2,
iterative = FALSE, doallstats = TRUE, lowmemory = FALSE, deblendtype = 'fit', psf = NULL,
fluxweight = 'sum', convtype = 'brute', convmode = 'extended', Ndeblendlim = Inf)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. As a convenience you can supply the output of profoundProFound of class profound, in which case any required input that is not explicitly set via the arguments will be inherited from the profoundProFound list.
segim	Integer matrix; a specified segmentation map of the image. This matrix *must* be the same dimensions as 'image' if supplied.
segstats	Data.frame, segmentation catalogue output from 'profoundProFound'.
groupim	Integer matrix; the grouped segmentation map. This matrix *must* be the same dimensions as 'image'. If missing then this is computed using profoundSegimGroup using the supplied 'segim'.
groupsegID	List; group information as output by 'profoundSegimGroup' or 'profoundProFound'. Must correspond to the supplied 'segstats'. If missing then this is computed using profoundSegimGroup using the supplied 'segim'.
sky	Numeric; the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
profound	List; object of class 'profound'. If this is provided then missing input arguments are taking directly from this structure (see Examples). As an added convenience, you can assign the profound object directly to the 'image' input.
magzero	Numeric scalar; the magnitude zero point.
df	Integer scalar; degrees of freedom for the non-parametric spline fitting. See smooth.spline.
radtrunc	Numeric scalar; the maximum allowed radius beyond the edge-most segment pixel to consider when deblending. Keeping this low (1-3) ensures segments do not gather flux from very distant regions of the group.
iterative	Logical; should each segment profile fit be subtracted as it goes along? TRUE tends to remove the pedestal from a large galaxy that has faint objects embedded on top.
doallstats	Logical; specifies whether the output catalogue is matched against all rows of the supplied 'segstats' (TRUE), or only the rows containing grouped (and therefore deblended) galaxies are returned and the core flux columns (see below)s.
lowmemory	Logical; if TRUE then a low memory mode of FluxDeblend will be used. This is quite a bit slower, so the default of FALSE is usually preferred unless you are running into serious memory issues.
deblendtype	Scalar character, either 'fit' (where the segments in the image are approximately fitted for deblending) or 'psf' (where a PSF must be provided to argument 'psf'). The former makes more sense for well resolved images (say optical)

where the main issue in the deblending is the overlapping of resolved flux components. The latter works better in the regime where the image is barely resolved beyond the PSF, and this dominate the uncertainty of the deblend.

`psf` Numeric matrix; must be provided if '`deblendtype`'='psf'. This should be a small image (usually square) of the image PSF/beam to use for deblending.

`fluxweight` Numeric scalar; only relevent when '`deblendtype`'='psf'. Either 'sum' (where the sum of the current segment weights the deblend solution), 'peak' (where only the peak pixel flux in the segment it used) or 'none' (no additional weighting is used). For very well resolved images 'sum' makes more sense, for barely resolved images 'peak' should be the safer option. Basically, you should pick the option that likely correlates best with the true (deblended) flux. This requires some thought on the user side (sorry!), but it might be a good idea to try both options and check the deblend quality.

`convtype` Scalar character, only relevent when '`deblendtype`'='psf'. Specifies the type on convolver to use. Available options are displayed by running `profitAvailableConvolvers`, but usually one of 'brute' or 'fftw'. The latter tends to be fastest when the supplied '`psf`' is much smaller than the '`image`' (factor greater than 4 in each dimension). As the sizes become comparable, fftw becomes faster since it scales better with the product of '`psf`' and '`image`' pixels.

`convmode` Scalar character, only relevent when '`deblendtype`'='psf'. Either 'extended' (the whole segment is convolved with the target PSF when determining the deblend) or 'psf' (the provided PSF is centred at the peak flux for deblending). Only relevent when '`deblendtype`'='psf'. The former makes more sense for well resolved images (say optical) where the main issue in the deblending is the overlapping of resolved flux components. The latter works better in the regime where the image is barely resolved beyond the PSF, and this dominate the uncertainty of the deblend.

`Ndeblendlim` Integer scalar; the limit for the number of pixels to consider in a deblending complex (Ngroup [number of segments in the group] x Npix [number of pixels in the group]). You might want to set this to a value similar to allowable machine memory (1e8 - 1e9 often) just to avoid extreme cases (e.g. large stars with lots of pixels and lots of segments).

Details

This routine only deblends with detected groups, so it is quite fast if the number of groups is quite low. If the image is more confused then this process can be quite slow.

Since there are a few ways to run it, here is some advice:

For clearly extended sources you probably want to run with deblendtype='fit', iterative=TRUE / deblendtype='psf', fluxweight='sum', convtype='extend'. The former works better for very complex source geometry (since it fits it), the latter might be a bit more stable though.

For poorly resolved images you probably want to run with deblendtype='psf', fluxweight='peak', convtype='psf'.

Value

A data.frame containing deblended flux information:

groupID	The group ID reference for the deblend (as taken from groupsegID)
segID	The segment ID reference for the deblend (as taken from groupsegID)
flux_db	Total flux (calculated using 'image'-'sky') in ADUs
mag_db	Total flux converted to mag using 'magzero'
N100_db	Total number of pixels in this segment, i.e. contains 100% of the flux
flux_segfrac	Fraction of group flux in this segment. If this is very low then it is likely harder to extract good quality fluxes (with or without deblending).
Qseg_db	Quality flag for deblended segment. This represents what fraction of the segment image flux is in our deblend model. Negative means the model misses flux, postive means it has too much. Nearer to 0 is better.
Qgroup_db	Quality flag for deblended group. This represents what fraction of the group image flux is in our deblend model. Negative means the model misses flux, postive means it has too much. Nearer to 0 is better.
beamcorrect	Maximal beam correction. This is not applied, but for isolated sources this is the amount you should multiply the flux (and mag etc) given the beam PSF. In crowded fields this will not work well since flux will not be conserved globally!

The below are only returned if 'doallstats'=TRUE:

flux_err_db	Estimated total error in the flux for the segment
mag_err_db	Estimated total error in the magnitude for the segment
flux_err_sky_db	Sky subtraction component of the flux error
flux_err_skyRMS_db	Sky RMS component of the flux error
flux_err_shot_db	Object shot-noise component of the flux error (only if 'gain' is provided)

Note

Given the large number of inputs required, this function effectively needs profoundProFound to be run first.

```

`profoundGainConvert` *Convert gain between mag-zero points*

Description

Simple function to update the gain (electrons/ADU) when changing between magnitude zero points. These gains are what should be passed to e.g. `profoundMakeSigma`.

Usage

```
profoundGainConvert(gain = 1, magzero = 0, magzero_new = 0)
```

Arguments

`gain`	Numeric scalar or vector; the current gain/s in electrons/ADU.
`magzero`	Numeric scalar or vector; the current magnitude zero point/s.
`magzero_new`	Numeric scalar or vector; the new magnitude zero point/s.

Details

A simple function that is mostly here to avoid silly conversion mistakes. The conversion is calculated as: gain*10^(-0.4*(magzero_new - magzero)), where an object magnitude can be calculated from ADU flux as -2.5*log10(flux_ADU)+magzero.

Value

Numeric scalar or vector; the new gain/s.

#For optical survey data typically images with gain~1 have a magzero~30:
profoundGainConvert(1,30,0)
```

`profoundGainEst` *Image Gain Estimator*

Description

High level function to estimate a rough value for the image gain in cases where you have no idea what the true image gain is. In practice this tends to be accurate to an order of magnitude and provides a reasonable lower limit for the true gain, which is good enough to make a rough first attempt at a sigma map.

Usage

```
profoundGainEst(image = NULL, mask = 0, objects = 0, sky = 0, skyRMS = 1)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse.
`mask`	Boolean matrix; optional, non galaxy parts of the image to mask out, where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as '`image`'.
`objects`	Boolean matrix; optional, object mask where 1 is object and 0 is sky. Pixels set to 0 are interpreted as sky, and set to zero for calculating object shot-noise. If provided, this matrix *must* be the same dimensions as '`image`'.
`sky`	Numeric scalar; user provided estimate of the absolute sky level. If this is not provided then it will be computed internally using `profoundSkyEst`.
`skyRMS`	Numeric scalar; user provided estimate of the RMS of the sky. If this is not provided then it will be computed internally using `profoundSkyEst`.

Details

This function makes use of the fact that a true Poisson distribution cannot generate samples below 0 and the distribution shape properties of the sky pixels. In practice this means the gain estimated is low as it can be. Once the ProFit fit has been made the gain estimated can be improved based on the residuals (assuming the model does a good job of subtracting the data).

Value

Numeric scalar; the estimated gain of the '`image`'.

---

profoundGetEllipse *Calculate single annulus properties of an iso-photal ellipse*

Description

Returns single ellipse properties for a specific set of pixels, assumed to be be a narrow range in flux (i.e. an iso-photal annulus).

Usage

```
profoundGetEllipse(x, y, z, xcen = NULL, ycen = NULL, scale = sqrt(2), pixscale = 1,
dobox = FALSE, plot=FALSE, ...)
```

Arguments

x	Numeric vector; x values of pixels. If this is a 3 column matrix then column 1 is used for 'x', column 2 is used for 'y' and column 3 is used for 'val', see Examples.
y	Numeric vector; y values of pixels.
z	Numeric vector; z values of pixels. This is effectively the height, and would be the pixel flux for an image.
xcen	Numeric scalar; the desired x centre of the ellipse. If this is not provided it is calculated internally.
ycen	Numeric scalar; the desired y centre of the ellipse. If this is not provided it is calculated internally.
scale	How should the standard ellipse covariance be scaled to create a geometric ellipse. The default of sqrt(2) is appropriate to create an ellipse that represents the location of an iso-photal contour of a galaxy.
pixscale	Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1 (default), then the output 'radhi', 'radlo' and 'radav' is in terms of pixels, otherwise they are in arcseconds.

dobox	Logical; should boxiness be computed? If FALSE then boxiness is fixed to be 0. If TRUE then boxiness is computed (and other parameters are refined) using a maximum likelihood method. This is more expensive to compute, so the default is FALSE.
plot	Logical; should an ellipse be drawn on the current plot? This plot is generated by the profoundDrawEllipse function.
...	Further arguments to be passed to profoundDrawEllipse. Only relevant is 'plot'=TRUE.

Details

The assumption is this function will largely be used by the profoundGetEllipses function, but it could be useful for computing the shape of a particular iso-photal contour (see Examples).

Value

A numeric vector with the following named elements:

xcen	The flux weighted x centre of the ellipse.
ycen	The flux weighted y centre of the ellipse.
radhi	The major axis extent of the ellipse (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec).
radlo	The minor axis extent of the ellipse (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec).
radav	The average radius of the ellipse (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec).
axrat	The axial ratio of the ellipse as given by 'radlo'/'radhi'.
ang	The angle of the ellipse in the usual ProFit sense, see profitMakeModel.
box	The boxiness of the ellipse in the usual ProFit sense, see profitMakeModel.
xsd	The flux weighted standard deviation in x (always in units of pix).
xsd	The flux weighted standard deviation in y (always in units of pix).
covxy	The flux weighted covariance in xy (always in units of pix).
corxy	The flux weighted correlation in xy (always in units of pix).

`profoundGetEllipses` *Calculate multiple annulus properties of iso-photal ellipses*

Description

Returns multiple ellipse properties for an image, assumed to be monotonically decreasing in flux from a bright centre (i.e. a classic galaxy).

Usage

```
profoundGetEllipses(image = NULL, segim = NULL, segID = 1, levels = 10, magzero = 0,
pixscale = 1, fixcen = TRUE, dobox = FALSE, plot = TRUE, ...)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse.
`segim`	Integer matrix; optional, the segmentation map of the image. This matrix *must* be the same dimensions as '`image`'.
`segID`	Integer scalar; optional, the desired '`segim`' segment to extract from the '`image`'.
`levels`	Integer scalar or vector. If a scalar this is the number of ellipse levels to extract from the '`image`'. If a vector this specfies the extremes of all fractional levels, i.e. it should generally start at 0 and end at 1 to capture all isophotal levels.
`magzero`	Numeric scalar; the magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega). If provided along with '`pixscale`' then the surface brightness output will represent mag/asec^2.
`pixscale`	Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1 (default), then the output '`radhi`', '`radlo`' and '`radav`' is in terms of pixels, otherwise they are in arcseconds. If provided along with '`magzero`' then the surface brightness output will represent mag/asec^2.
`fixcen`	Logical; should the ellipse centres be fixed to a common flux weighted centre?

dobox	Logical; should boxiness be computed? If FALSE then boxiness is fixed to be 0. If TRUE then boxiness is computed (and other parameters are refined) using a maximum likelihood method. This is more expensive to compute, so the default is FALSE.
plot	Logical; should a diagnostic plot be generated? This plot is generated by the profoundGetEllipsesPlot function.
...	Further arguments to be passed to profoundGetEllipsesPlot. Only relevant if 'plot'=TRUE.

Details

This higher level function provides an easy way to extract iso-photal ellipses from an image of a galaxy. How it works somewhat replicates IRAF's ellipse, but it is really present to offer useful initial guesses for bulge and disk geometric properties. It certainly does not guarantee to return the same solution as IRAF (in fact I am not exactly aware of how IRAF computes its ellipses).

Internally it works by rank ordering the pixels of the galaxy and dividing these into equi-spaced quantiles of flux (so each annulus will approximately sum to the same amount of flux). This means that the error for each ellipse will be approximately constant. For each annulus it then runs profoundGetEllipse to compute the ellipse properties of what is assumed to be a fairly narrow annulus of pixels. The implicit assumption is that the galaxy flux more-or-less monotonically decreases from the centre, and dividing pixels like this will assure the extraction of common iso-photal ellipses. This assumption works well within the inner 90% of a galaxy's flux, but isophotes can be quite noisy once the galaxy flux gets close to the sky RMS level. This said, the ellipse returned will on average make sense, and ellipses tend to overlap only in very extreme cases (where the geometry is highly non-elliptical or there are close contaminants).

Value

A list containing:

ellipses	A data.frame of ellipse properties ordered by radius (see below).
segellipses	Integer matrix; the ellipse-wise segmentation map matched pixel by pixel to 'image'. This allows you to see which specific pixels used to compute each ellipse annulus in 'ellipses', where the number in the segmentation map refers to 'segellipseID'.

'ellipses' is a data.frame of ellipse properties ordered by radius. It has the following columns

segellipseID	The ellipse segment ID that refers to the segmentation map 'segellipses'.
fluxfrac	The approximate fraction of galaxy flux contained within this ellipse.
xcen	The flux weighted x centre of the ellipse.
ycen	The flux weighted y centre of the ellipse.
radhi	The major axis extent of the ellipse (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)..
radlo	The minor axis extent of the ellipse (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)..

radav	The average radius of the ellipse (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)..
axrat	The axial ratio of the ellipse as given by 'radlo'/'radhi'.
ang	The angle of the ellipse in the usual ProFit sense, see profitMakeModel.
box	The boxiness of the ellipse in the usual ProFit sense, see profitMakeModel.
xsd	The flux weighted standard deviation in x (always in units of pix).
ysd	The flux weighted standard deviation in y (always in units of pix).
covxy	The flux weighted covariance in xy (always in units of pix).
corxy	The flux weighted correlation in xy (always in units of pix).
flux	The flux contained in the segmented pixels associated with this ellipse.
N	The number of segmented pixels associated with this ellipse.
SB	The mean surface brightness of the pixels associated with this ellipse (if 'pixscale' has been set correctly then this column will represent mag/asec^2, otherwise it will be mag/pix^2).

lines(rlocs, profoundFlux2SB(bulge, pixscale=0.2), col='red')
lines(rlocs, profoundFlux2SB(disk, pixscale=0.2), col='blue')
lines(rlocs, profoundFlux2SB(bulge+disk, pixscale=0.2), col='green')

## End(Not run)
```

`profoundGetEllipsesPlot` *Create diagnostic plot of estimated iso-photal ellipses*

Description

Generates a useful plot merging a rapidly changing colour mapping with the estimated ellipses.

Usage

```
profoundGetEllipsesPlot(image = NULL, ellipses = NULL, segim = NULL, segID = 1,
segellipseID = "all", pixscale = 1, col = rep(rainbow(10, s = 0.5), 4), border = "auto",
lty = 'auto', lwd = 'auto', ...)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse.
`ellipses`	Data.frame; the ellipse information, but in practice the 'ellipse' list output of `profoundGetEllipses`.

segim	Integer matrix; optional, the segmentation map of the image. This matrix *must* be the same dimensions as 'image'.
segID	Integer scalar; optional, the desired 'segim' segment to extract from the 'image'.
segellipseID	Integer vector; the segellipseID to be plotted. The default of 'all' will display all ellipses.
pixscale	Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). This should only be used if the radii columns in 'ellipses' have already been scaled by the pixel scale.
col	The colour palette to be used for the background 'image'. The default is chosen to be high contrast, to make it easier to compare the computed ellipses with the underlying isophotes.
border	The colour of the ellipse border drawn by draw.ellipse. If 'auto' then a sensible default is chosen.
lty	The line type of the ellipse border drawn by draw.ellipse. If 'auto' then a sensible default is chosen ('lty'=1 within the 90% flux radius and 'lty'=2 outside).
lwd	The line width of the ellipse border drawn by draw.ellipse. If 'auto' then a sensible default is chosen ('lwd'=0.5 within the 50% flux radius, 'lwd'=1 above the 50% flux radius, except for the annuli at 50%/90% which is 'lwd'=2).
...	Further arguments to be passed to magimage.

Details

The default options should create useful diagnostics, but there are lots of potential plots that can be made with the outputs of profoundGetEllipses, including e.g. making plots of how various parameters behave with radius, which can give helpful insight to starting parameters for bulge and disk profiles. The user is encouraged to experiment.

Value

No value is returned, this function is run purely for the side effect of making a diagnostic plot.

```

`profoundIm` *Image Transformations*

Description

Various image transformation functions that assist in exploring data. These all require the `imager` package to be installed.

Usage

```
profoundImBlur(image = NULL, sigma = 1, plot = FALSE, ...)
profoundImGrad(image = NULL, sigma = 1, plot = FALSE, ...)
profoundImDiff(image = NULL, sigma = 1, plot = FALSE, ...)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse.
`sigma`	Numeric scalar; standard deviation of the blur.
`plot`	Logical; should a `magimage` plot of the output be generated?
`...`	Further arguments to be passed to `magimage`. Only relevant is '`plot`'=TRUE.

Value

Numeric matrix; a new image the same size as '`image`', with the relevant transform applied.

For `profoundImBlur` the output is a smoothed version of the '`image`'.

For `profoundImGrad` the output is the magnitude of the gradient of the smoothed version of the '`image`'.

For `profoundImDiff` the output is the original '`image`' minus the smoothed version of the '`image`'.

`profoundMag2Mu` *Magnitude to Surface Brightness Conversions*

Description

Functions to convert total magnitudes to surface brightness and vica-versa. These are provided to allow models to be either specified by total magnitude or mean surface brightness within Re. The latter is a useful way of specifying a disk model since surface brightness does not span a huge range.

Usage

```
profoundMag2Mu(mag = 15, re = 1, axrat = 1, pixscale = 1)
profoundMu2Mag(mu = 17, re = 1, axrat = 1, pixscale = 1)
```

Arguments

`mag`	Total magnitude of the 2D Sersic profile.
`mu`	Mean surface brightness within Re of the 2D Sersic profile.
`re`	Effective radii of the 2D Sersic profile.
`axrat`	Axial ratio of Sersic profile defined as minor-axis/major-axis, i.e. 1 is a circle and 0 is a line.
`pixscale`	The pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1, then the surface brightness is interpreted in terms of pixels, otherwise it is interpreted in terms of arcseconds^2.

Value

profoundMag2Mu returns the mean surface brightness within Re of the 2D Sersic profile.

profoundMag2Mu returns total magnitude of the 2D Sersic profile.

`profoundMakeSegim` *Watershed Image Segmentation*

Description

A mid level utility to achieve decent quality image segmentation. It uses a mixture of image smoothing and watershed segmentation propagation to identify distinct objects for use in, e.g., `profitSetupData` (where the '`segim`' list item output of `profoundMakeSegim` would be passed to the '`segim`' input of `profitSetupData`). For most user cases, people should use the higher level `profoundProFound` function.

Usage

```
profoundMakeSegim(image = NULL, mask = NULL, objects = NULL, skycut = 1, pixcut = 3,
tolerance = 4, ext = 2, reltol = 0, cliptol = Inf, sigma = 1, smooth = TRUE, SBlim = NULL,
magzero = 0, gain = NULL, pixscale = 1, sky = NULL, skyRMS = NULL, header = NULL,
verbose = FALSE, plot = FALSE, stats = TRUE, rotstats = FALSE, boundstats = FALSE,
offset = 1, sortcol = "segID", decreasing = FALSE, watershed = 'ProFound', ...)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
`mask`	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as '`image`'.
`objects`	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as '`image`'.
`skycut`	Numeric scalar; the lowest threshold to make on the '`image`' in units of the sky RMS. Passed to `profoundMakeSegim`.
`pixcut`	Integer scalar; the number of pixels required to identify an object. Passed to `profoundMakeSegim`.
`tolerance`	Numeric scalar; the minimum height of the object in the units of sky RMS between its highest point (seed) and the point where it contacts another object (checked for every contact pixel). If the height is smaller than the tolerance, the object will be combined with one of its neighbours, which is the highest. The range 1-5 offers decent results usually. This is passed to '`tolerance`' in 'EBImage', or '`abstol`' in 'ProFound' (see '`watershed`').
`ext`	Numeric scalar; radius of the neighbourhood in pixels for the detection of neighbouring objects. Higher value smooths out small objects.

reltol	Numeric scalar; only relevant for 'watershed'='ProFound'. A modifier to the 'tolerance', modifying it by the ratio of the segment peak flux divided by the saddle point flux to the power 'reltol'. The default means the 'reltol' has no effect since this modifier becomes 1. A larger value of 'reltol' means segments are more aggressively merged together.
cliptol	Numeric scalar; only relevant for 'watershed'='ProFound'. If ('image'-'sky')/optionskyRMS is above this level where segments touch then they are always merged, regardless of other criteria. When thinking in terms of sky RMS, values between 20-100 are probably appropriate for merging very bright parts of stars back together in optical data.
sigma	Numeric scalar; standard deviation of the blur used when 'smooth'=TRUE.
smooth	Logical; should smoothing be done on the target 'image'? If present, this will use the imblur function from the imager package. Otherwise it will use the gblur function from the EBImage package with a warning. These functions are very similar in output, but not strictly identical.
SBlim	Numeric scalar; the mag/asec^2 surface brightness threshold to apply. This is always used in conjunction with 'skycut', so set 'skycut' to be very large (e.g. Inf) if you want a pure surface brightness threshold for the segmentation. 'magzero' and 'pixscale' must also be present for this to be used.
magzero	Numeric scalar; the magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega). If provided along with 'pixscale' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.
gain	Numeric scalar; the gain (in photo-electrons per ADU). This is only used to compute object shot-noise component of the flux error (else this is set to 0).
pixscale	Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1 (default), then the output is in terms of pixels, otherwise it is in arcseconds. If provided along with 'magzero' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.
sky	User provided estimate of the absolute sky level. If this is not provided then it will be computed internally using profoundSkyEst. Can be a scalar (value uniformly applied) or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!
skyRMS	User provided estimate of the RMS of the sky. If this is not provided then it will be computed internally using profoundSkyEst. Can be a scalar (value uniformly applied to full 'sigma' map) or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
header	Full FITS header in table or vector format. If this is provided then the segmentations statistics table will gain 'RAcen' and 'Decen' coordinate outputs. Legal table format headers are provided by the read.fitshdr function or the 'hdr' list output of read.fits in the astro package; the 'hdr' output of readFITS in the FITSio package or the 'header' output of magcutoutWCS. Missing header keywords are printed out and other header option arguments are used in these cases. See magWCSxy2radec.
verbose	Logical; should verbose output be displayed to the user? Since big image can take a long time to run, you might want to monitor progress.

plot	Logical; should a diagnostic plot be generated? This is useful when you only have a small number of sources (roughly a few hundred). With more than this it can start to take a long time to make the plot!
stats	Logical; should statistics on the segmented objects be returned? If 'magzero' and 'pixscale' have been provided then some of the outputs are computed in terms of magnitude and mag/asec^2 rather than flux and flux/pix^2 (see Value).
rotstats	Logical; if TRUE then the 'asymm', 'flux_reflect' and 'mag_reflect' are computed, else they are set to NA. This is because they are very expensive to compute compared to other photometric properties.
boundstats	Logical; if TRUE then various pixel boundary statistics are computed ('Nedge', 'Nsky', 'Nobject', 'Nborder', 'edge_frac', 'edge_excess' and 'FlagBorder'). If FALSE these return NA instead (saving computation time).
offset	Integer scalar; the distance to offset when searching for nearby segments (used in profoundSegimStats).
sortcol	Character; name of the output column that the returned segmentation statistics data.frame should be sorted by (the default is segID, i.e. segment order). See below for column names and contents.
decreasing	Logical; if FALSE (default) the segmentation statistics data.frame will be sorted in increasing order, if TRUE the data.frame will be sorted in decreasing order.
watershed	Character; the funciton to use to achieve the watershed deblend. Allowed options are 'EBImage' for EBImage::watershed, and 'ProFound' for the new Rcpp implementation included with the ProFound package.
...	Further arguments to be passed to magimage. Only relevant is 'plot'=TRUE.

Details

To use this function you will need to have EBImage installed. Since this can be a bit cumbersome on some platforms (given its dependencies) this is only listed as a suggested package. You can have a go at installing it by running:

> source("http://bioconductor.org/biocLite.R")

> biocLite("EBImage")

Linux users might also need to install some non-standard graphics libraries (depending on your install). If you do not have them already, you should look to install **jpeg** and **tiff** libraries (these are apparently technically not entirely free, hence not coming by default on some strictly open source Linux variants).

The profoundMakeSegim function offers a high level internal to R interface for making quick segmentation maps. The defaults should work reasonably well on modern survey data (see Examples), but should the solution not be ideal try modifying these parameters (in order of impact priority): 'skycut', 'pixcut', 'tolerance', 'sigma', 'ext'.

Value

A list containing:

segim	Integer matrix; the segmentation map matched pixel by pixel to 'image'.

objects	Logical matrix; the object map matched pixel by pixel to 'image'. 1 means there is an object at this pixel, 0 means it is a sky pixel. Can be used as a mask in various other functions that require objects to be masked out.
sky	The estimated sky level of the 'image'.
skyRMS	The estimated sky RMS of the 'image'.
segstats	If 'stats'=TRUE this is a data.frame (see below), otherwise NULL.
header	The header provided, if missing this is NULL.
call	The original function call.

If 'stats'=TRUE then the function profoundSegimStats is called and the 'segstats' part of the returned list will contain a data.frame else NULL (see profoundSegimStats).

profoundMakeSegimExpand

Segmentation Map Expansion and Dilation

Description

A high level utility to achieve decent quality image segmentation based on the expansion of a pre-existing segmentation map. It uses smoothing and local flux weighted comparisons to grow the current segmentation map so as to better identify distinct objects for use in, e.g., `profitSetupData`.

Usage

```
profoundMakeSegimExpand(image = NULL, segim = NULL, mask = NULL, objects = NULL,
skycut = 1, SBlim = NULL, magzero = 0, gain = NULL, pixscale = 1, sigma = 1,
smooth = TRUE, expandsigma = 5, expand = "all", sky = NULL, skyRMS = NULL, header = NULL,
verbose = FALSE, plot = FALSE, stats = TRUE, rotstats = FALSE, boundstats = FALSE,
offset = 1, sortcol = "segID", decreasing = FALSE, ...)
profoundMakeSegimDilate(image = NULL, segim = NULL, mask = NULL, size = 9, shape = "disc",
expand = "all", magzero = 0, gain = NULL, pixscale = 1, sky = 0, skyRMS = 0,
header = NULL, verbose = FALSE, plot = FALSE, stats = TRUE, rotstats = FALSE,
boundstats = FALSE, offset = 1, sortcol = "segID", decreasing = FALSE, ...)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
`segim`	Integer matrix; required, the segmentation map of the image. This matrix *must* be the same dimensions as '`image`'.
`mask`	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as '`image`'.
`objects`	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as '`image`'.
`skycut`	Numeric scalar; the lowest threshold to make on the '`image`' in units of the skyRMS. Since we are restricted to expanding out pre-existing segmentation regions we can usually afford to make this value lower than the equivalent in `profoundMakeSegim`.
`SBlim`	Numeric scalar; the magnitude/arcsec^2 surface brightness threshold to apply. This is always used in conjunction with '`skycut`', so set '`skycut`' to be very large (e.g. Inf) if you want a pure surface brightness threshold for the segmentation. '`magzero`' and '`pixscale`' must also be present for this to be used.
`magzero`	Numeric scalar; the magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega). If provided along with '`pixscale`' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.

gain	Numeric scalar; the gain (in photo-electrons per ADU). This is only used to compute object shot-noise component of the flux error (else this is set to 0).
pixscale	Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1 (default), then the output is in terms of pixels, otherwise it is in arcseconds. If provided along with 'magzero' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.
sigma	Numeric scalar; standard deviation of the blur used when 'smooth'=TRUE.
smooth	Logical; should smoothing be done on the target 'image'? If present, this will use the imblur function from the imager package. Otherwise it will use the gblur function from the EBImage package with a warning. These functions are very similar in output, but not strictly identical.
expandsigma	Numeric scalar; standard deviation of the blur used when expanding out the 'segim'. Roughly speaking if 'skycut' is set to a low number (say -5) then the expansion will not be prevented by the local sky level and it will grow by the number of pixels specified by 'expandsigma'.
expand	Integer vector; specifies which segmentation regions should be expanded by the segID integer reference. If left with the default 'expand'='all' then all segments will be expanded.
size	Integer scalar; the size (e.g. width/diameter) of the dilation kernel in pixels. Should be an odd number else will be rounded up to the nearest odd number. See makeBrush.
shape	Character scalar; the shape of the dilation kernel. See makeBrush.
sky	User provided estimate of the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!
skyRMS	User provided estimate of the RMS of the sky. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
header	Full FITS header in table or vector format. If this is provided then the segmentations statistics table will gain 'RAcen' and 'Decen' coordinate outputs. Legal table format headers are provided by the read.fitshdr function or the 'hdr' list output of read.fits in the astro package; the 'hdr' output of readFITS in the FITSio package or the 'header' output of magcutoutWCS. Missing header keywords are printed out and other header option arguments are used in these cases. See magWCSxy2radec.
verbose	Logical; should verbose output be displayed to the user? Since big image can take a long time to run, you might want to monitor progress.
plot	Logical; should a diagnostic plot be generated? This is useful when you only have a small number of sources (roughly a few hundred). With more than this it can start to take a long time to make the plot!
stats	Logical; should statistics on the segmented objects be returned?
rotstats	Logical; if TRUE then the 'asymm', 'flux_reflect' and 'mag_reflect' are computed, else they are set to NA. This is because they are very expensive to compute compared to other photometric properties.

boundstats	Logical; if TRUE then various pixel boundary statistics are computed ('Nedge', 'Nsky', 'Nobject', 'Nborder', 'edge_frac', 'edge_excess' and 'FlagBorder'). If FALSE these return NA instead (saving computation time).
offset	Integer scalar; the distance to offset when searching for nearby segments (used in profoundSegimStats).
sortcol	Character; name of the output column that the returned segmentation statistics data.frame should be sorted by (the default is segID, i.e. segment order). See below for column names and contents.
decreasing	Logical; if FALSE (default) the segmentation statistics data.frame will be sorted in increasing order, if TRUE the data.frame will be sorted in decreasing order.
...	Further arguments to be passed to magimage. Only relevant is 'plot'=TRUE.

Details

The basic behaviour of profoundMakeSegimExpand and profoundMakeSegimDilate is to intelligently expand out image segments already identified by, e.g., profoundMakeSegim.

The profoundMakeSegimExpand defaults should work reasonably well on modern survey data (see Examples), but should the solution not be ideal try modifying these parameters (in order of impact priority): 'skycut' (or 'SBlim'), 'expandsigma', 'sigma'.

profoundMakeSegimDilate is similar in nature to the pixel growing objmask routine in IRAF (see the 'ngrow' and 'agrow' description at http://iraf.noao.edu/projects/ccdmosaic/objmasks/objmasks.html). This similarity was discovered after implementation, but it is worth noting that the higher level curve of growth function profoundProFound is not trivially replicated by other astronomy tools.

The main difference between profoundMakeSegimExpand and profoundMakeSegimDilate is the former grows the expansion a bit more organically, whereas the latter always gives new pixels to the brighter object if in doubt. That said, profoundMakeSegimDilate often gives very similar solutions and runs about 10+ times faster, so might be the only option for larger images.

Value

A list containing:

segim	Integer matrix; the segmentation map matched pixel by pixel to 'image'.
objects	Logical matrix; the object map matched pixel by pixel to 'image'. 1 means there is an object at this pixel, 0 means it is a sky pixel. Can be used as a mask in various other functions that require objects to be masked out.
sky	The estimated sky level of the 'image'. profoundMakeSegimExpand only).
skyRMS	The estimated sky RMS of the 'image'. profoundMakeSegimExpand only).
segstats	If 'stats'=TRUE this is a data.frame (see below), otherwise NULL.
header	The header provided, if missing this is NULL.
SBlim	The surface brightness limit of detected objects. Requires at least 'magzero' to be provided and 'skycut'>0, else NULL. profoundMakeSegimExpand only.
call	The original function call.

If 'stats'=TRUE then the function profoundSegimStats is called and the 'segstats' part of the returned list will contain a data.frame with columns (else NULL):

segID	Segmentation ID, which can be matched against values in 'segim'
uniqueID	Unique ID, which is fairly static and based on the xmax and ymax position
xcen	Flux weighted x centre
ycen	Flux weighted y centre
xmax	x position of maximum flux
ymax	y position of maximum flux
RAcen	Flux weighted degrees Right Ascension centre (only present if a 'header' is provided)
Deccen	Flux weighted degrees Declination centre (only present if a 'header' is provided)
RAmax	Right Ascension of maximum flux (only present if a 'header' is provided)
Decmax	Declination of maximum flux (only present if a 'header' is provided)
sep	Radial offset between the cen and max definition of the centre (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
flux	Total flux (calculated using 'image'-'sky') in ADUs
mag	Total flux converted to mag using 'magzero'
cenfrac	Fraction of flux in the brightest pixel
N50	Number of brightest pixels containing 50% of the flux
N90	Number of brightest pixels containing 90% of the flux
N100	Total number of pixels in this segment, i.e. contains 100% of the flux
R50	Approximate elliptical semi-major axis containing 50% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
R90	Approximate elliptical semi-major axis containing 90% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
R100	Approximate elliptical semi-major axis containing 100% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
SB_N50	Mean surface brightness containing brightest 50% of the flux, calculated as 'flux'*0.5/'N50' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
SB_N90	Mean surface brightness containing brightest 90% of the flux, calculated as 'flux'*0.9/'N90' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
SB_N100	Mean surface brightness containing all of the flux, calculated as 'flux'/'N100' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
xsd	Weighted standard deviation in x (always in units of pix)
ysd	Weighted standard deviation in y (always in units of pix)
covxy	Weighted covariance in xy (always in units of pix)

corxy	Weighted correlation in xy (always in units of pix)
con	Concentration, 'R50'/'R90'
asymm	180 degree flux asymmetry (0-1, where 0 is perfect symmetry and 1 complete asymmetry)
flux_reflect	Flux corrected for asymmetry by doubling the contribution of flux for asymmetric pixels (defined as no matching segment pixel found when the segment is rotated through 180 degrees)
mag_reflect	'flux_reflect' converted to mag using 'magzero'
semimaj	Weighted standard deviation along the major axis, i.e. the semi-major first moment, so ~2 times this would be a typical major axis Kron radius (always in units of pix)
semimin	Weighted standard deviation along the minor axis, i.e. the semi-minor first moment, so ~2 times this would be a typical minor axis Kron radius (always in units of pix)
axrat	Axial ratio as given by min/maj
ang	Orientation of the semi-major axis in degrees. This has the convention that 0= | (vertical), 45= \, 90= - (horizontal), 135= /, 180= | (vertical)
signif	Approximate singificance of the detection using the Chi-Square distribution
FPlim	Approximate false-positive significance limit below which one such source might appear spuriously on an image this large
flux_err	Estimated total error in the flux for the segment
mag_err	Estimated total error in the magnitude for the segment
flux_err_sky	Sky subtraction component of the flux error
flux_err_skyRMS	Sky RMS component of the flux error
flux_err_shot	Object shot-noise component of the flux error (only if 'gain' is provided)
sky_mean	Mean flux of the sky over all segment pixels
sky_sum	Total flux of the sky over all segment pixels
skyRMS_mean	Mean value of the sky RMS over all segment pixels
Nedge	Number of edge segment pixels that make up the outer edge of the segment
Nsky	Number of edge segment pixels that are touching sky
Nobject	Number of edge segment pixels that are touching another object segment
Nborder	Number of edge segment pixels that are touching the 'image' border
Nmask	Number of edge segment pixels that are touching a masked pixel (note NAs in 'image' are also treated as masked pixels)
edge_frac	Fraction of edge segment pixels that are touching the sky i.e. 'Nsky''Nedge', higher generally meaning more robust segmentation statistics
edge_excess	Ratio of the number of edge pixels to the expected number given the elliptical geometry measurements of the segment. If this is larger than 1 then it is a sign that the segment geometry is irregular, and is likely a flag for compromised photometry

flag_border — A binary flag telling the user which 'image' borders the segment touches. The bottom of the 'image' is flagged 1, left=2, top=4 and right=8. A summed combination of these flags indicate the segment is in a corner touching two borders: bottom-left=3, top-left=6, top-right=12, bottom-right=9.

profoundMakeSegimExpand(image, segim$segim, plot=TRUE, skycut=0)
profoundMakeSegimExpand(image, segim$segim, plot=TRUE, skycut=-Inf, sigma=3)

profoundMakeSegimDilate(image, segim$segim, plot=TRUE, size = 15)
profoundMakeSegimDilate(image, segim$segim, plot=TRUE, size = 21)

#This expansion process is a *much* better idea then simply setting the original skycut
#to a low value like 1/0:
profoundMakeSegim(image, plot=TRUE, skycut = 1)
profoundMakeSegim(image, plot=TRUE, skycut = 0)

## End(Not run)
```

---

profoundMakeSegimPropagate

Propagate Identified Segments

Description

Propagates all identified segments across the full image, only ignoring masked regions. This serves to identify which segment every pixel is most likely to belong to using a number of image related criteria. Uses EBImage's propagate function to do the grunt work.

Usage

```
profoundMakeSegimPropagate(image = NULL, segim = NULL, objects = NULL, mask = NULL,
sky = 0, lambda = 1e-04, plot = FALSE, ...)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
segim	Integer matrix; required, the segmentation map of the image. This matrix *must* be the same dimensions as 'image'.
objects	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as 'image'.
mask	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
sky	User provided estimate of the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!
lambda	A numeric value. The regularization parameter used in the metric, determining the trade-off between the Euclidean distance in the image plane and the contribution of the gradient of x. See Details.
plot	Logical; should a diagnostic plot be generated? This is useful when you only have a small number of sources (roughly a few hundred). With more than this it can start to take a long time to make the plot!
...	Further arguments to be passed to magimage. Only relevant is 'plot'=TRUE.

Details

This function propgates out the identified segments into the rest of the 'image', only region identified in the 'mask' will not be assigned to a segment. To assign pixels a mixture of the Euclidian distance and the local gradient is used (as described below). The purpose of this routine is to identify all pixels in the image with their most likely segment (whether nominally object or sky pixel). The true sky pixels identified as belonging to a segment should also provide the best possible local estimate of the sky level.

For internal completeness, the below description is taken almost verbatim from the EBImage propagate function.

The method operates by computing a discretized approximation of the Voronoi regions for given seed points on a Riemann manifold with a metric controlled by local 'image' features.

Under this metric, the infinitesimal distance d between points v and v+dv is defined by:

d^2 = ((t(dv)*g)^2 + lambda*t(dv)*dv)/(lambda + 1) , where g is the gradient of 'image' x at point v.

'lambda' controls the weight of the Euclidean distance term. When 'lambda' tends to infinity, d tends to the Euclidean distance. When 'lambda' tends to 0, d tends to the intensity gradient of the 'image'.

The gradient is computed on a neighborhood of 3x3 pixels.

Segmentation of the Voronoi regions in the vicinity of flat areas (having a null gradient) with small values of 'lambda' can suffer from artifacts coming from the metric approximation.

Value

A list containing two images:

propim	The propagated segmentation map including the original segments identified.
propim_sky	The propagated segmentation map removing the original segments identified (these pixels are set to 0).

profoundMakeSigma *Make a Sigma Map*

Description

A utility function to construct a ProFit legal sigma map that can be input to profitSetupData.

Usage

```
profoundMakeSigma(image = NULL, objects = NULL, sky = 0, skyRMS = 0, readRMS = 0,
darkRMS = 0, skycut = 0, gain = 1, image_units = 'ADU', sky_units = 'ADU',
read_units = 'ADU', dark_units = 'ADU', output_units = 'ADU', plot = FALSE, ...)
```

Arguments

image	Numeric matrix; required, the image we want to analyse.
objects	Boolean matrix; optional, object mask where 1 is object and 0 is sky. Pixels set to 0 are interpreted as sky, and set to zero for calculating object shot-noise. If provided, this matrix *must* be the same dimensions as 'image'.
sky	Numeric; the absolute sky level. Consider using the sky output from profoundSkyEst or profoundMakeSkyGrid. Can be a scalar (value uniformly applied to full 'sigma' map) or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!
skyRMS	Numeric; the RMS of the sky. Consider using the skyRMS output from profoundSkyEst or profoundMakeSkyGrid. Can be a scalar (value uniformly applied to full 'sigma' map) or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
readRMS	Numeric; the RMS of the read-noise. If you have estimated the sky RMS from the image directly this should not be necessary since it naturally captures this component. Can be a scalar (value uniformly applied to full 'sigma' map) or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
darkRMS	Numeric; the RMS of the dark-current-noise. If you have estimated the sky RMS from the image directly this should not be necessary since it naturally captures this component. Can be a scalar (value uniformly applied to full 'sigma' map) or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
skycut	How many multiples of 'skyRMS' above the 'sky' to start calculating shot-noise based on the 'gain' scaling of the 'image'. If you are missing an object mask You almost certainly do not want this to be below 0 (else you will reduce the level of the sigma map just due to fluctuations in the sky), and in practice this should probably be set in the range 1-3.
gain	Numeric; the gain (in photo-electrons per ADU). For a very rough estimate consider using the gain output from profoundGainEst. Can be a scalar (value uniformly applied to full 'sigma' map) or a matrix matching the dimensions of 'image' (allows values to vary per pixel).

image_units	Character; the units of the 'image'. Must either be 'ADU' for generic astronomical data units, or 'elec' for photo-electrons.
sky_units	Character; the units of 'sky' and 'skyRMS'. Must either be 'ADU' for generic astronomical data units (the same type and scaling as per 'image'), or 'elec' for photo-electrons.
read_units	Character; the units of 'read'. Must either be 'ADU' for generic astronomical data units (the same type and scaling as per 'image'), or 'elec' for photo-electrons.
dark_units	Character; the units of 'dark'. Must either be 'ADU' for generic astronomical data units (the same type and scaling as per 'image'), or 'elec' for photo-electrons.
output_units	Character; the units of the output sigma map. Must either be 'ADU' for generic astronomical data units (the same type and scaling as per 'image'), or 'elec' for photo-electrons.
plot	Logical; should a magimage plot of the output be generated?
...	Further arguments to be passed to magimage. Only relevant is 'plot'=TRUE.

Details

This is a simple utility function, but useful for beginners if they are unsure of how the error terms should be propagated (in short: in quadrature).

Value

Numeric matrix; a sigma map the same size as 'image'. This should be appropriate for feeding into profitSetupData.

profoundMakeSky *Calculate Sky Maps*

Description

The high level function computes the absolute sky and sky RMS level over an image at a scale defined locally by the 'box' parameter. This coarse map can then be used to compute sky/skyRMS values for the local sky anywhere on an image. This function uses profoundSkyEstLoc to calculate the sky statistics for the subset boxcar regions.

Usage

```
profoundMakeSkyMap(image = NULL, objects = NULL, mask = NULL, sky = 0,
 box = c(100,100), grid = box, skytype = "median", skyRMStype = "quanlo", sigmasel = 1,
 skypixmin = prod(box)/2, boxadd = box/2, boxiters = 0, conviters = 100, doclip = TRUE,
  shiftloc = FALSE, paddim = TRUE, cores = 1)

profoundMakeSkyGrid(image = NULL, objects = NULL, mask = NULL, sky = 0,
  box = c(100,100), grid = box, skygrid_type = 'new', type = 'bicubic',
 skytype = "median", skyRMStype = "quanlo", sigmasel = 1, skypixmin = prod(box)/2,
 boxadd = box/2, boxiters = 0, conviters = 100, doclip = TRUE, shiftloc = FALSE,
  paddim = TRUE, cores = 1)

profoundMakeSkyBlur(image = NULL, objects = NULL, box = 100,
  sigma = mean(box)*(4/pi)/sqrt(12))
```

Arguments

image	Numeric matrix; required, the image we want to analyse.
objects	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as 'image'.
mask	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
sky	User provided estimate of the absolute sky level. Can be a scalar (value uniformly applied) or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted! The sky statistics will be computed with 'sky' removed, and then the input 'sky' is added back on. By this route it is possible to refine a best effort sky measurement iteratively. For images with extreme gradients this might achieve a better solution, and in particular a more accurate 'skyRMS' map, where it might be systematically high if the gradient is strong across the scale of the requested 'box' (since this will appear to be enhanced variance).
box	Integer vector; the dimensions of the box car filter to estimate the sky with.

`grid` Integer vector; the resolution of the background grid to estimate the sky with. By default this is set to be the same as the 'box'.

`skygrid_type` Character scalar; either 'new' (the new ADACS C++ sky grid code) or 'old' (the older R based code as used for ProFound <= v1.10).

`type` Character scalar; either "bilinear" for bilinear interpolation or "bicubic" for bicubic interpolation. The former creates sharper edges, the later is guaranteed to be first order differentiable. As of `ProFound` v1.13.0 we use the IntpAkimaUniform2 version available from www.geometrictools.com under a Boost 1.0 license (replacing the older `Akima` package and ADACS implementations, the former being memory intensive and the latter caused some small numerical artefacts).

`skytype` Character scalar; the type of sky level estimator used. Allowed options are 'median' (the default), 'mean', 'mode' and 'converge' (see `profoundSkyEstLoc` for an explanation of what these estimators do). In all cases this is the estimator applied to unmasked and non-object pixels. If 'doclip'=TRUE then the pixels will be dynamically sigma clipped before the estimator is run.

`skyRMStype` Character scalar; the type of sky level estimator used. Allowed options are 'quanlo' (the default), 'quanhi', 'quanboth', 'sd' and 'converge' (see `profoundSkyEstLoc` for an explanation of what these estimators do). In all cases this is the estimator applied to unmasked and non-object pixels. If 'doclip'=TRUE then the pixels will be dynamically sigma clipped before the estimator is run.

`sigmasel` Numeric scalar; the quantile to use when trying to estimate the true standard-deviation of the sky distribution. If contamination is low then the default of 1 is about optimal in terms of S/N, but you might need to make the value lower when contamination is very high.

`skypixmin` Numeric scalar; the minimum number of sky pixels desired in our cutout. The default is that we need half the original number of pixels in the 'box' to be sky.

`boxadd` Integer vector; the dimensions to add to the 'box' to capture more pixels if 'skypixmin' has not been achieved.

`boxiters` Integer scalar; the number of 'box'+'boxadd' iterations to attempt in order to capture 'skypixmin' sky pixels. The default means the box will not be grown at all.

`conviters` Integer scalar; number of iterative sky convergence steps when 'skytype' = 'converge' and/or 'skyRMStype' = 'converge'.

`doclip` Logical; should the unmasked non-object pixels used to estimate to local sky value be further sigma-clipped using `magclip`? Whether this is used or not is a product of the quality of the objects extraction. If all detectable objects really have been found and the dilated objects mask leaves only apparent sky pixels then an advanced user might be confident enough to set this to FALSE. If an doubt, leave as TRUE.

`shiftloc` Logical; should the cutout centre for the sky shift from 'loc' if the desired 'box' size extends beyond the edge of the image? (See `magcutout` for details).

`paddim` Logical; should the cutout be padded with image data until it meets the desired 'box' size (if 'shiftloc' is true) or padded with NAs for data outside the image boundary otherwise? (See `magcutout` for details).

cores	Integer scalar; how many cores should be used to calculate sky properties of the image. Given the overhead for parallel computing, this should probably only be above 1 for larger images.
sigma	Numeric scalar; the standard deviation of the blur (positive) used for smoothing the sky pixels to make a sky map (see isoblur in imager package).

Details

The matrix generated will have many fewer pixels than the original 'image', so it will need to be interpolated back onto the full grid by some mechanism in order to have 1-1 values for the sky and sky RMS.

Value

profoundMakeSkyMap produces a list of two lists. The first (called 'sky') contains a list of x,y,z values for the absolute sky, and second (called 'skyRMS') contains a list of x,y,z values for the sky RMS. The grids returned are as coarse as the 'grid' option provided.

profoundMakeSkyGrid produces a list of two lists. The first (called 'sky') is a matrix of values for the absolute sky. The second (called 'skyRMS') is a matrix of values for the absolute sky RMS. The image matrices returned are pixel matched to the input 'image' using the specified interpolation scheme.

profoundMakeSkyBlur produces a matrix of the sky map (there is no sky RMS component). To work well sources must be well masked either with NA in the 'image', or using the 'objects' matrix. Since this function can only provide the additive sky, it cannot be used in isolation to computer the necessary sky information (we need the sky RMS map for profoundProFound), but it might offer a better smoother sky (so replacing the sky component of profoundMakeSkyGrid.

magimage(skybil$sky-skybic$sky, magmap=FALSE)
magimage(skybil$skyRMS-skybic$skyRMS, magmap=FALSE)

## End(Not run)
```

`profoundMakeStack` *Stack Images*

Description

Stacks multiple images based on their signal-to-noise.

Usage

```
profoundMakeStack(image_list = NULL, sky_list = NULL, skyRMS_list = NULL, magzero_in = 0,
magzero_out = 0, masking = 'and')
```

Arguments

`image_list`	List; each list element is a numeric matrix representing the image to be stacked.
`sky_list`	List; each list element is a numeric matrix representing the sky to be subtracted.
`skyRMS_list`	List; each list element is a numeric matrix representing the sky-RMS to weight the stack with.
`magzero_in`	Numeric vector; the input mag-zero points. If length 1 then it is assumed all input frames have the same mag-zero point.
`magzero_out`	Numeric scalar; the output mag-zero point desired.
`masking`	Character scalar; what to do with masked pixels (NAs in the 'image'). If 'or' a pixel is masked if *any* of the images being stacked have a masked pixel (NA in the 'image_list') at that location, if 'and' then a pixel is masked if *all* of the images being stacked have a masked pixel at that location.

Details

The stack is actually done based on variance weighting. In pseudo code:

stack=0 stackRMS=0 for(i in 1:length(image_list)) stack=stack+(image_list[[i]]-sky_list[[i]])/(skyRMS_list[[i]]^2) sky_stack=sky_stack+(image_list[[i]]^2)

stack=stack*sky_stack/(length(skyRMS_list)^2)

The output is explictly sky subtracted (so the sky is now 0 everywhere by definition as far as profoundProFound is concerned). The stacked sky is not returned. However, it can be computed by running profoundMakeStack again, but passing the sky list originally passed to the 'sky_list' argument to the 'image_list' argument instead, and not providing any input to the 'sky_list' argument (or setting this to 0).

Value

A list containing:

image	Numeric matrix; the variance-weighted sky-subtracted stacked image. Masked pixels are NA.
skyRMS	Numeric matrix/scalar; the sky RMS image/value of the final stacked image
magzero	The mag-zero point of the stacked image.

magimage(profoundMakeStack(list(im1, im2, im3), masking='and')$image)
```

---

profoundMultiBand *Multi Band ProFound Photometry*

Description

Run multiband ProFound photometry either with loaded data, or images on a local disk.

Usage

```
profoundMultiBand(inputlist = NULL, dir = "", segim = NULL, mask = NULL,
detectbands = "r", multibands = c("u", "g", "r", "i", "z"), iters_det = 6, iters_tot = 0,
sizes_tot = 5, magzero = 0, gain = NULL, box = 100, grid=box, boxadd=box/2, app_diam = 1,
bandappend = multibands, totappend = "t", colappend = "c", grpappend = 'g', dotot = TRUE,
docol = TRUE, dogrp = TRUE, deblend = FALSE, groupstats = FALSE,
groupby_det = 'segim_orig', groupby_mul = 'segim_orig', keepsegims = FALSE,
masking = 'and', ...)
```

Arguments

inputlist	A list of already loaded images. Typically of the type loaded in from FITS files by the astro package's read.fits function, or the FITSio package's readFITS function. If using the 'inputlist' parameter the length of the list must be the same length as 'multibands' (and the related parameters).
dir	If 'inputlist' is left as NULL then profoundMultiBand will instead try to load in FITS images from the directory specified by 'dir'. The images in the directory must have names like 'multibands'[i].fits etc (so with the defaults names like u.fits and g.fits would be okay). Since 'multibands' effectively specifies the file names much more complicated naming can be used and passed in, but it is also used by default for naming the catalogue column outputs, so shorter names/references are likely to be preferable there (i.e. mag_ut is simpler than mag_KiDS_VST_ut etc). This can be over-ridden by using 'bandappend'.
segim	Integer matrix; a specified segmentation map of the image. This matrix *must* be the same dimensions as the detection image/s if supplied. If this option is used then profoundMultiBand will not compute its initial segmentation map using profoundMakeSegim, which is then dilated. Instead it will use the one passed through 'segim' and dilate this according to the 'iters_det' argument (so set this to 0 if you want the 'segim' to be used as is).
mask	Boolean matrix or integer scalar; optional, parts of the image to mask out (i.e. ignore). If a matrix is provided, this matrix *must* be the same dimensions as 'image' where 1 means mask out and 0 means use for analysis. if a scalar is provided it indicates the exact 'image' values that should be treated as masked (e.g. by setting masked pixels to 0 or -999). The latter achieves the same effect as setting masked 'image' pixels to NA, but allows for the fact not all programs can

produce R legal NA values. Not that for detection masking is an OR operator, so if a pixel is masked on any input 'image' it will be masked in the detection 'image'. This is the more conservative way to treat the issue of multiband masking.

detectbands — Character vector; the names of the detection bands that will be stacked using profoundMakeStack and then analysed with the provided settings with profoundProFound to make a reference segmentation map for further multi band photometry. These bands must be present in 'multibands'. Can be a scalar (i.e. a single band is used). If set to 'get' then it will use all legal FITS files in the target directory. If set to 'all' then it will use all 'multibands' inputs.

multibands — Character vector; the names of the target multi band photometry images. If set to 'get' then it will use all legal FITS files in the target directory. If using the 'inputlist' parameter the length of the list must be the same length as 'multibands'. 'magzero' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. If specified, 'gain' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. If specified, 'catappend' must either the same length and order as 'multibands'.

iters_det — Integer scalar; the maximum number of curve of growth dilations that should be made to the detection image. This needs to be large enough to capture all the flux for sources of interest, but increasing this will increase the computation time for profoundProFound. If this is set to 0 then the undilated 'segim' image, whether provided or computed internally via profoundMakeSegim, will be used instead.

iters_tot — Integer vector; the maximum number of curve of additional growth dilations that should be made above the dilated detection segmentation map for multi band total colour photometry. This is only relevant if 'dotot'=TRUE. This should not be set too high (and might even be 0, the default) since the detection image should generally be fairly deep. 'iters_tot' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'.

sizes_tot — Integer vector; the size (e.g. width/diameter) of the dilation kernel in pixels. Should be an odd number else will be rounded up to the nearest odd number. See makeBrush. Passed to profoundMakeSegimDilate. 'sizes_tot' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'.

magzero — Numeric vector; the magnitude zero point of the images being used. 'magzero' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. See also profoundProFound.

gain — Numeric vector; the gain of the images being used. 'gain' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. See also profoundProFound.

box — Numeric vector; the sky estimate box size of the images being used. 'box' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. See also profoundProFound.

grid — Integer vector; the resolution of the background grid to estimate the sky with. By default this is set to be the same as the 'box'. 'grid' must either be length

1 (in which this value is used for all bands), or the same length and order as 'multibands'. See also profoundProFound.

boxadd — Integer vector; the dimensions to add to the 'box' to capture more pixels if 'skypixmin' has not been achieved. By default this is set to be the same as the 'box'/2. 'boxadd' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. See also profoundProFound.

app_diam — Numeric vector; the diameter in arc seconds to use for pseudo aperture photometry. This will use the appropriate pixel scale to convert the aperture into image units. The psuedo aperture photometry is output to columns 'flux_app' and 'mag_app' in 'cat_tot'. 'app_diam' must either be length 1 (in which this value is used for all bands), or the same length and order as 'multibands'. See also profoundProFound.

bandappend — Character vector; characters to be appended per band in the output multi band photometry catalogues. The default will create columns with names like mag_ut (total) and mag_uc (colour).

totappend — Character scalar; character to be appended in the output multi band total photometry catalogue (cat_tot). The default will create columns with names like mag_ut and R50_ut.

colappend — Character scalar; character to be appended in the output multi band colour photometry catalogue (cat_col). The default will create column with names like mag_uc and R50_uc.

grpappend — Character scalar; character to be appended in the grouped segment multi band total photometry catalogue (cat_tot). The default will create columns with names like mag_ug and R50_ug.

dotot — Logical; should dilated segment total photometry be computed for the bands specified in 'multibands'? This will return closer to total magnitudes in all target bands.

docol — Logical; should non-dilated segment colour photometry be computed for the bands specified in 'multibands'? This will return better colour magnitudes in all target bands (i.e. more accurate differences between bands) and will typically under-represent the total photometry.

dogrp — Logical; should group segment photometry be computed for the bands specified in 'multibands'? This might be useful for re-assembling large galaxies that are broken up at a later date. 'boundstats' must also be set to TRUE if 'dogrp'=TRUE is set.

deblend — Logical; should total segment flux be deblended using profoundFluxDeblend and these columns appended to the end of the output segstats? This only applies to the 'cat_tot' output.

groupstats — Logical; if TRUE then the IDs of grouped segments is calculated for the detection image via profoundSegimGroup and output to the returned object 'group'. By default this option is linked to 'boundstats', i.e. it is assumed if you want boundary statistics then you probably also want grouped object IDs returned.

groupby_det — Character scalar; How should the grouped segmentation map be formed that will be used to produce the 'cat_grp' output? Options are either via 'segim' or 'segim_orig'. 'segim' will create more groups, 'segim_orig' will have less.

groupby_mul	Character scalar; How should the grouped segmentation map be formed that will be used to produce the multi-band deblending for 'cat_tot' and 'cat_col' outputs? Options are either via 'segim' or 'segim_orig'. 'segim' will create more groups, 'segim_orig' will have less.
keepsegims	Logical; if TRUE then profoundMultiBand will return a list of per band segmentation maps in 'segimlist'. This is useful since they can be slightly different per band.
masking	Character scalar; what to do with masked pixels (NAs in the 'image'). If 'or' a pixel is masked if *any* of the images being stacked have a masked pixel (NA in the 'image_list') at that location, if 'and' then a pixel is masked if *all* of the images being stacked have a masked pixel at that location.
...	Further arguments to be passed to all instances of profoundProFound. E.g. if the sky 'SBdilate' is set to a value (default is NULL) this will be propogated to all of the multi band photometry runs of profoundProFound.

Details

This very high level function simplifies a sequence of function calls that we found users typically needed to make, but when scripted they were prone to mistakes and made multi band photometry scripts hard to maintain.

In the simplest sense this script runs profoundProFound on each detection band and uses this information to make a stacked image using profoundMakeStack. profoundProFound is then run on this stacked image to make a deep segmentation map. For good total photometry the segim object from this output is used, and allowed to further dilate to account for different observing conditions (i.e. PSFs). For good colour photometry the segim_orig object from this output is used. Only the profoundSegimStats output is kept for the target multi band images, so not all of the outputs from profoundProFound since this is usually unnecessary when operating in this mode, and creates a huge quantity of data.

Value

An object list of class 'profoundmulti' containing:

pro_detect	The full output of profoundProFound for the detection image (of class 'profound').
cat_tot	If 'dotot'=TRUE, the dilated total photometry for the target bands. Effectively the output of profoundSegimStats run on pro_detect$segim.
cat_col	If 'docol'=TRUE, the non-dilated colour photometry for the target bands. Effectively the output of profoundSegimStats run on pro_detect$segim_orig.
cat_grp	If 'dogrp'=TRUE, the group segment photometry for the target bands. Effectively the output of profoundSegimStats run on pro_detect$group$groupim.
segimlist	If 'keepsegims'=TRUE then this object contains a list of per band total segmentation maps. This is useful since they can be slightly different per band.
detectbands	Character vector; the names of the detection bands used.
multibands	Character vector; the names of the target multi band photometry images used.
call	The original function call.

date	The date, more specifically the output of date.
time	The elapsed run time in seconds.

```

`profoundPixelCorrelation` *Pixel to pixel correlation statistics*

Description

Returns the x and y dimension pixel-to-pixel correlation (often called covariance) at various scales, optionally returning a diagnostic plot.

Usage

```
profoundPixelCorrelation(image = NULL, objects = NULL, mask = NULL, sky = 0, skyRMS = 1,
lag = c(1:9, 1:9 * 10, 1:9 * 100, 1:9 * 1000, 1:9 * 10000), fft = TRUE, plot = FALSE,
ylim=c(-1,1), log='x', grid=TRUE, ...)
profoundSkySplitFFT(image = NULL, objects = NULL, mask = NULL, sky = 0, skyRMS = 1,
skyscale = 100, profound = NULL)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
`objects`	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as image.
`mask`	Boolean matrix; optional, parts of the 'image' to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
`sky`	Numeric; the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
`skyRMS`	Numeric; the RMS of the sky. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel).
`lag`	Interger verctor; the pixel lags to measure pixel-to-pixel correlation over the x and y dimensions.

fft	Logical; if TRUE the 2D FFT is computed and the modulus image matrix is returned to 'fft' and the ('image'-'sky')/'skyRMS' is return to 'image_sky', if FALSE the 'fft' and 'image_sky' objects are returned as NULL. 'object' and 'mask' pixels are used to identify pixels to replace as described below.
plot	Logical; should a x/y correlation diagnostic plot be generated?
ylim	Numeric vector; range of data to display (see magplot for details). Only relevant if 'plot'=TRUE.
log	Character scalar; log axis arguments to be passed to plot. E.g. use 'x', 'y', 'xy' or 'yx' as appropriate (see magplot for details). Only relevant if 'plot'=TRUE.
grid	Logical; indicates whether a background grid should be drawn onto the plotting area (see magplot for details). Only relevant if 'plot'=TRUE.
skyscale	Numeric scalar; required, the pixel scale that the FFT should split the provided 'image_sky' at. This should be chosen so as to separate out true sky modes and possible sources still in the sky. Too small and real sources will be put into the 'sky_lo' image returned, so larger is usually safer.
profound	List; object of class 'profound'. If this is provided then missing input arguments are taking directly from this structure (see Examples). As an added convenience, you can assign the profound object directly to the 'image' input.
...	Further arguments to passe to magplot. Only relevant if 'plot'=TRUE.

Details

profoundPixelCorrelation:

All statistics are computed on ('image'-'sky')/'skyRMS'. If 'fft'=TRUE this matrix is return to 'image_sky'.

The function is useful to assessing a number of image attributes. For one things it tells you whether all spatial variance has been detected and removed at small scales as objects (e.g. using profoundProFound), or at larger scales as sky fluctuations. Assuming the object detection and sky removal has worked well, the remaining pixel-to-pixel correlation likely represents instrument level covariance. In practice nearly all processes produce positive pixel correlation, but it is not impossible that negative correlation can be introduced during the reduction process, particularly when over-subtracting the sky around bright stars.

For calculating the raw pixel-to-pixel correlation (as returned by 'cortab') 'mask' and 'object' pixels are ignored, so correlation is only considered where both pixels are flagged as un-masked sky pixels. The 2D image FFT output ('fft') replaces masked or object pixels with Normally distributed noise after the input 'image' has had the 'sky' subtracted and divided by the 'skyRMS'. Note that this means the FFT generated is partly stochastic (it will differ a bit each time it is run), but in practice it will be quite persistant for large scales (the centre) and stochastic at small scales (around the edge of the FFT image).

The slightly weird units used for the k modes of the FFT (see the value section below) is convenient because it means we can correctly label the FFT image in integer pixels counting out from the centre. The way to interpret the k-modes is that if you have an image of size L=356x356 then you can find the pixel representing a particular scale by computing L/S, where S is the scale of interest in pixels. I.e. S=356 is the mode representing the full image length scale since L/S=1 and can be found 1 pixel from the centre, whilst S=178/89 represents the half/quarter image scale and can be

found at pixels L/S=2 or 4 (respectively) from the centre. From this reasoning we have Nyqvist sampling at 356/2=178 pixels from the centre (i.e. the edges of the FFT image).

The relative standard-deviations returned in 'cortab' are calculated by taking the standard-deviation of the lagged pixel differences of ('image'-'sky')/'skyRMS' and dividing through by sqrt(2). This means for well behaved data they should be 1, and the dashed lines on the diagnostic plot should fall on 1.

profoundSkySplitFFT:

The FFT split output separates the provided image into hi k ('sky_hi') and low k ('sky_lo') modes. The idea is that 'sky_lo' might represent additional sky with complex structure (not captured by the bicubic/bilinear extimated sky) that still needs to be subtracted off the image, whilst 'sky_hi' might contain some as yet un-subtracted sources.

In principle profoundSkySplitFFT can be run with any image, but the separation into the low and high k modes is not easily interpretable in the presence of many real objects since they will dominate the power at all scales (trust me on this).

Value

profoundPixelCorrelation:

A list containing three objects:

- cortab: A data.frame containing:
  - lag: The pixel lag
  - corx: The correlation in the x-dimension
  - cory: The correlation in the y-dimension
  - corx_neg: The correlation of +ve-sky versus +ve-sky pixels in x
  - cory_neg: The correlation of +ve-sky versus +ve-sky pixels in y
  - corx_pos: The correlation of -ve-sky sky versus -ve-sky sky pixels in x
  - cory_pos: The correlation of -ve-sky sky versus -ve-sky sky pixels in y
  - corx_diff: corx_pos - corx_neg
  - cory_diff: cory_pos - cory_neg
  - relsdx: The pixel lag implied relative standard-deviation in x
  - relsdy: The pixel lag implied relative standard-deviation in y
- fft: if 'fft'=TRUE this object contains a list containing x, y, and z. If 'fft'=FALSE it is NULL. x and y contain the k mode values of the 2D FFT in units of (2.pi)/(L.pix), where L is the original dimensions of the image being Fourier transformed in x and y respectively. z contains the power component of the 2D FFT image as a numeric matrix; the modulus of the 2D FFT of the 'image' with the same dimensions. We use the optical representation, where the DC (or k=0) mode is in the absolute centre. This means larger scale produce power in the central parts of the FFT image, and smaller scales produce power in the outer parts of the FFT image.
- image_sky: Numeric matrix; if 'fft'=TRUE this object contains the ('image'-'sky')/'skyRMS', if 'fft'=FALSE it is NULL.
- cor_err_func: the error function between 'N100' (the number of pixels in the segment) and the relative flux error. This will never be less than 0, and can be near 1 for small segments in highly correlated data (which is what should be expected).

profoundSkySplitFFT:
A list containing three numeric matrices:

- skyThe new sky estimate, defined as the input 'sky'+'sky_lo'.
- sky_loThe low k modes extracted from the objects masked 'image'-'sky'.
- sky_hiThe high k modes extracted from the objects masked 'image'-'sky'.

# For super added convenience you can also un:

newsky=profoundSkySplitFFT(profound)

# Old versus new sky:

magimage(profound$sky)
magimage(newsky$sky)

# Original image, old sky subtraction and new sky subtraction (pretty subtle!):

magimage(image$imDat)
magimage(image$imDat-profound$sky)
magimage(image$imDat-newsky$sky)

# Be warned, you need a reasonable estimate of the sky and objects before running this.
# If we run on the original image that even the high/low k modes look very odd:
```

```
magimage(profoundSkySplitFFT(image$imDat)$sky_lo)
magimage(profoundSkySplitFFT(image$imDat)$sky_hi)

## End(Not run)
```

---

profoundResample *Resample Images*

Description

A utility function to resample input PSFs to different pixel scales on a consistent flux conserving manner.

Usage

```
profoundResample(image, pixscale_old = 1, pixscale_new = 1, type = "bicubic",
fluxscale = "image", recentre = FALSE)
```

Arguments

image	Numeric matrix; required, the image we want to resample.
pixscale_old	Numeric scalar; the current (old) pixel scale of the supplied 'image'.
pixscale_new	Numeric scalar; the target (new) pixel scale of the desired output.
type	Character scalar; either "bilinear" for bilinear interpolation or "bicubic" for bicubic interpolation (default, requires akima package).
fluxscale	Character scalar; how the output image should be scaled. Either 'image' (the sum of output 'image' will exactly qual the sum of the input 'image'), 'pixscale' (the sum of the output pixels is scaled by the ratio of pixel scales squared, which means the output 'image' will approximately equal the sum of the input 'image'), or 'norm' (the output 'immge' will sum to equal exactly 1).
recentre	Logical; should the final 'image' have its peak flux value in the centre of the image? This is useful for resampling PSFs, where we do not want small centring errors. When the input 'image' is highly off centre, or not a simple image of a PSF, then this option might cause image artefacts.

Details

Mostly used for resampling PSFs to different pixel scales.

Value

Numeric matrix; the desired resampled 'image'. This will have roughly dim('image')[1]*'pixscale_old'/'pixscale_new' by dim('image')[2]*'pixscale_old'/'pixscale_new' pixels. The interpolation

profoundSegimExtend *Find Additional Image Segments*

Description

This function takes a target segmentation map, and finds additional sources on a target image. This might be useful where you want to do matched aperture photometry, but there is the possibility that the target image might have genuine additional sources that are not in your current segmentation map. This might cause issues with the sky estimation etc (even if you do not actually care about getting photometry for these additional sources).

Usage

```
profoundSegimExtend(image = NULL, segim = NULL, mask = segim, ...)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
segim	Integer matrix; required, the segmentation map of the 'image'. This matrix *must* be the same dimensions as 'image'.
mask	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
...	Further arguments to be passed to profoundProFound.

Details

This function is mostly useful if you are chaining together a script of detection images based on certain bands that are then run on data which might have very different (and previously undetected) astrophysical sources.

Value

Integer matrix; the segmentation map matched pixel by pixel to 'image' and 'segim'. Newly identified segments are appended in number to the input 'segim', so if the maximum previous segment ID was 10, the new sources would start from 11 etc.

profoundSegimFix *Interactive Segment Fixing Tool*

Description

This function will launch an interactive session to let users reassemble segments of groups etc. The idea is that you might have very large galaxies that are hard to keep together with profoundProFound settings that also work well at separating close sources. Using this tool allows users to quickly put things back together in an easy fashion.

Usage

```
profoundSegimFix(image = NULL, segim = NULL, mask = NULL, sky = NULL, profound = NULL,
loc = NULL, box = 400, segID_merge = list(), col = 'magenta', pch = 4, cex = 2,
crosshair = FALSE, crosscex = 5, alpha_seg = 0.3, happy_default = TRUE,
continue_default = TRUE, open_window = TRUE, allow_seg_modify = FALSE, segID_max = NULL,
...)
```

Arguments

image	Required, the image we want to display. If a numeric matrix is passed in then magimage is used to display the image. If the 'image' has components R/G/B then then magimageRGB is used to display a colour image.
segim	Integer matrix; required, the segmentation map of the 'image'. This matrix *must* be the same dimensions as 'image'.
mask	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
sky	User provided estimate of the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!
profound	List; object of class 'profound'. If this is provided then missing input arguments are taking directly from this structure. As an added convenience, you can assign the profound object directly to the 'image' input.
loc	Numeric vector; the [x,y] location where we want to cutout the image.
box	Numeric vector; the dimensions of the box to cut out from 'image' centred on 'loc'.
segID_merge	Integer list; each list element should specify collections of segments to be merged. This will be updated by the fixing session, and the updated results are returned as part of the output list.
col	Colour of the overlaid click positions.
pch	Point type of the overlaid click positions.
cex	Size of the overlaid click positions.
crosshair	Logical; should a crosshair be placed in the centre of the image to guide the eye?
crosscex	Numeric scalar; size of the overlaid crosshair.
alpha_seg	Numeric scalar; the alpha transparency of the overlaid segment polygons.
happy_default	Logical; what should the default answer be to whether you are happy with the current fix (default is TRUE, i.e. yes).
continue_default	Logical; what should the default answer be to whether you what to fix more segments (default is TRUE, i.e. yes).
open_window	Logical; should a new Quartz or X11 window be opened. When looping through different image regions this should probably be FALSE. It is here because it is a very bad idea to try to do this using the R-Studio plot window- it does not properly support interactive plotting and will not show the click positions.
allow_seg_modify	Logical; should users be allowed to add and delete segments. Since this behaviour will modify the input 'segim' it is not always desirable. To be safe, it is off (FALSE) by default. See Details.

segID_max — Integer; the maximum segment ID to assume for the input 'segim' when adding or replacing segments (so only relevant if 'allow_seg_modify'=TRUE), where the default segID for a new segment becomes 'segID_max' + 1. Providing this speeds things up since it can be slow to compute for very large images (tenths of second for 10k x 10k). If set to 'auto' then it will check the input 'segim', if left at the default NULL it will check the available segim when it is creating a new segment. Since this will be on a segmentation image subset when specifying a box, this might mean the segID is not unique on the larger input 'segim', but it will be unique on the cut down one being processed internally, and the ones returned ('segim' and 'segim_start').

... — Additional arguments to be passed to magimage or magimageRGB as appropriate.

Details

Basic instructions:

Follow the prompts when you run the function (see Example).

1) Click on the segments you want to merge together into one segment and hit ESC when done.

2) You will then be asked if you are happy. If you are then type 'y' in the command prompt and hit enter. If not type 'n' and hit enter. The former will merge the segments, the latter will undo the most recent round of fixes and let you start again.

3) You will then be asked if you want to continute fixing. If you want to continue fixing other broken segments in the current image then type 'y' in the command prompt and hit enter. If you want to stop type 'n' and hit enter. The former will then prompt you to fix more segments with another round of clicking, the latter will stop the fixing session and return the results as they stand.

Features:

You cannot merge segments into the sky! All clicks on the sky are ignored, and they will not produce any of the multi-click results discussed below.

Currently fixed segment complexes (as per the internal version of 'segID_merge', with both the input fixes and the fixes made in the current session) are shown by overlaid polygons showing the original colours of the merged segments. This stops you from fixing complexes that have already been fixed.

If you see one of these coloured polygon complexes and do not like the solution you can click once in it and hit ESC in the plot window. This will tell the code to unpick the complex and return all filled segments back to their original solution. You can then try to fix it again, if needed.

If you make a number of clicks and then change your mind, click on the unwanted segment twice and make some other this will ignore the segment when merging- this allows you to fix silly click errors by clicking again.

If you click on any segment three times and hit ESC in the plot window it will tell the code that you are both definitely happy *and* that you want to stop fixing segments, ending the session instantly. This allows you to make rapid progress when doing lots of easy fixes since you do not need to then type anything at all into the command prompt (which slows down progress).

If 'allow_seg_modify'=TRUE and you just click on a segment twice and nothing else it will flag it for having its segID changed or potentially deleted by setting to 0 (sky). It will ask what segID you want for the segment, where the default of "auto" will make a new segID one larger than the current maximum. You can specify your own choice manually, where if you use a current segID it

will merge the sources. It is possible to delete the segment by setting the segID when asked to "0", which means it will become sky.

If 'allow_seg_modify'=TRUE and you click on the sky once and hit ESC you will enter the segment creation mode. Now all clicks made will form a concave polygon, with the contained pixels becoming a new segment with a new segID ('segID_max' + 1, or user specified). This new segment will be registered on both the 'segim_start' and 'segim' outputs to ensure internal consistency. Double clicking a single segment (see above) also enters this mode, and the segment is changed in the same manner as if it were drawn manually. In both cases it is possible to delete segments contained within the polygon simply by setting the segID when asked to "0", which means it will become sky. In this manner you can delete potentially many at once by drawing round large groups of unwanted segments.

Value

List containing:

segim	Numeric matrix; fixed version of the segmentation map. If a cutout has been requested this will be for just the cutout section.
segim_start	Numeric matrix; reference starting segmentation map.
segID_merge	List; fixed version of the list of segIDs to be merged. Usefully, this can be directly passed into profoundSegimKeep (see Examples).
segID_max	Integer; the current maximum segment ID in the output 'segim'. This should only be modified compared to the input 'segim' if new segments have be drawn on the image.

It is always the case that 'segim_start' combined with 'segID_merge' will produce 'segim' via profoundSegimKeep. We provide 'segim_start' for reference since the segment creation mode (see Details above) will also modify the base segmentation map in order to guarantee the internal consistency. This means the output 'segim_start' and differ from the input 'segim_start', but only if new segments have been manually drawn.

segim=profound$segim)

#Assuming you made some fixes you can also recreate the fixed segim using the output
# \option{segID_merge})(i.e. you only really need to save \option{segID_merge}):

fixedRGB2=profoundSegimKeep(segim=profound$segim, segID_merge=fixedRGB$segID_merge)

#Check things look the same:

profoundSegimPlot(image=VST_r$imDat, segim=fixedRGB$segim)
profoundSegimPlot(image=VST_r$imDat, segim=fixedRGB2)

#We can now feed this back into ProFound for our best final effort:

profound2=profoundProFound(VST_r, segim=fixedRGB$segim, plot=TRUE, SBdilate=1)

#The object at 300, 300 is the new merged object (if you have merged the main galaxy).
#On a local run this had segID=6, old mag=15.5, new mag=15.2 (i.e. flux increase of 30%).

## End(Not run)
```

`profoundSegimGroup` *Create Segmentation Groups*

Description

Given an input segmentation map, returns a map of groups of touching segments as well as the IDs of segments within each group.

Usage

```
profoundSegimGroup(segim = NULL)
```

Arguments

`segim`	Integer matrix; required, the segmentation map.

Details

To use this function you will need to have EBImage installed. Since this can be a bit cumbersome on some platforms (given its dependencies) this is only listed as a suggested package. You can have a go at installing it by running:

> source("http://bioconductor.org/biocLite.R")

> biocLite("EBImage")

Linux users might also need to install some non-standard graphics libraries (depending on your install). If you do not have them already, you should look to install **jpeg** and **tiff** libraries (these are apparently technically not entirely free, hence not coming by default on some strictly open source Linux variants).

`profoundSegimGroup` uses the `bwlabel` function from EBImage.

Value

A list containting the following structures:

`groupim`	An map of the unique groups identified in the input '`segim`', where the groupID is the same as the lowest valued segID in the group.
`groupsegID`	A data.frame of lists giving the segIDs of segments in each group.

The data.frame returned by '`groupsegID`' is a slightly unusal structure to see in R, but it allows for a compact manner of storing uneven vectors of grouped segments. E.g. you might have a massive group containing 30 other segments and many groups containing a single segment. Padding a normal matrix out to accommodate the larger figure would be quite inefficient. It contains the following:

`groupID`	Group ID, which can be matched against values in '`groupim`'
`segID`	An embedded list of segmentation IDs for segments in the group. I.e. each list element of '`segID`' is a vector (see Examples for clarity).
`Ngroup`	The total number of segments that are in the group.
`Npix`	The total number of pixels that are in the group.

`profoundSegimInfo` *Image Segmentation Statistics*

Description

Basic summary statistics for image segments, e.g. aperture parameters, fluxes and surface brightness estimates. These might provide useful first guesses to ProFit fitting parameters (particularly '`flux`', '`axrat`' and '`ang`').

Usage

```
profoundSegimStats(image = NULL, segim = NULL, mask = NULL, sky = NULL, skyRMS = NULL,
magzero = 0, gain = NULL, pixscale = 1, header = NULL, sortcol = "segID",
decreasing = FALSE, rotstats = FALSE, boundstats = FALSE, offset = 1, cor_err_func = NULL,
app_diam = 1)
profoundSegimPlot(image = NULL, segim = NULL, mask = NULL, sky = NULL, header = NULL,
col = rainbow(max(segim), end=2/3), profound = NULL, add = FALSE, ...)
```

Arguments

`image`	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
`segim`	Integer matrix; required, the segmentation map of the '`image`'. This matrix *must* be the same dimensions as '`image`'.
`mask`	Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as '`image`'.
`sky`	User provided estimate of the absolute sky level. Can be a scalar or a matrix matching the dimensions of '`image`' (allows values to vary per pixel). This will be subtracted off the '`image`' internally, so only provide this if the sky does need to be subtracted!

skyRMS — User provided estimate of the RMS of the sky. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel).

magzero — Numeric scalar; the magnitude zero point. What this implies depends on the magnitude system being used (e.g. AB or Vega). If provided along with 'pixscale' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.

gain — Numeric scalar; the gain (in photo-electrons per ADU). This is only used to compute object shot-noise component of the flux error (else this is set to 0).

pixscale — Numeric scalar; the pixel scale, where pixscale=asec/pix (e.g. 0.4 for SDSS). If set to 1 (default), then the output is in terms of pixels, otherwise it is in arcseconds. If provided along with 'magzero' then the flux and surface brightness outputs will represent magnitudes and mag/asec^2.

header — Full FITS header in table or vector format. If this is provided then the segmentations statistics table will gain 'RAcen' and 'Decen' coordinate outputs. Legal table format headers are provided by the read.fitshdr function or the 'hdr' list output of read.fits in the astro package; the 'hdr' output of readFITS in the FITSio package or the 'header' output of magcutoutWCS. Missing header keywords are printed out and other header option arguments are used in these cases. See magWCSxy2radec.

sortcol — Character; name of the output column that the returned segmentation statistics data.frame should be sorted by (the default is segID, i.e. segment order). See below for column names and contents.

decreasing — Logical; if FALSE (default) the segmentation statistics data.frame will be sorted in increasing order, if TRUE the data.frame will be sorted in decreasing order.

rotstats — Logical; if TRUE then the 'asymm', 'flux_reflect' and 'mag_reflect' are computed, else they are set to NA. This is because they are very expensive to compute compared to other photometric properties.

boundstats — Logical; if TRUE then various pixel boundary statistics are computed ('Nedge', 'Nsky', 'Nobject', 'Nborder' 'Nmask', 'edge_frac', 'edge_excess' and 'FlagBorder'). If FALSE these return NA instead (saving computation time). Note by construction 'Nedge' = 'Nobject' + 'Nsky' + 'Nborder'. If you want to adjust specifically for 'Nmask' then 'Nsky' = 'Nsky' - 'Nmask'.

offset — Integer scalar; the distance to offset when searching for nearby segments.

col — Colour palette; the colours to map the segment IDs against. This is by default the magnitude using a rainbow palette, going from red for bright segments, via green, to blue for faint segments.

profound — List; object of class 'profound'. If this is provided then missing input arguments are taking directly from this structure. As an added convenience, you can assign the profound object directly to the 'image' input.

cor_err_func — Function; the error function between 'N100' (the number of pixels in the segment) and the relative flux error. Most likely the 'cor_err_func' output of profoundPixelCorrelation.

app_diam — Numeric scalar; the diameter in arc seconds to use for pseudo aperture photometry. This will use the appropriate pixel scale to convert the aperture into image units. The psuedo aperture photometry is output to columns 'flux_app' and 'mag_app' in 'segstats'.

add	Logical; should just the segment contours be added to the current image? This allows for complex colouring of different segments to be achieved by adding various overlays.
...	Further arguments to be passed to magimage.

Details

profoundSegimStats provides summary statistics for the individual segments of the image, e.g. properties of the apertures, and the sum of the flux etc. This is used inside of profoundMakeSegim and profoundMakeSegimExpand, but it may be useful to use separately if manual modifications are made to the segmentation, or two segmentations (e.g. a hot and cold mode segmentation) need to be combined.

The interpretation of some of these outputs will depend a lot on the data being analysed, so it is for the user to decide on sensible next steps (e.g. using the outputs to select stars etc). One output of interest might be 'flux_reflect'. This attempts to correct for missing flux where segments start colliding. This probably returns an upper limit to the flux since in some regions it can even be double counted if the two sources that have colliding segmentation maps are very close together and similar in brightness, so somewhere between 'flux' and 'flux_reflect' the truth probably lies. If you want a better estimate of the flux division then you should really be using the profiling routine of ProFit.

profoundSegimPlot is useful when you only have a small number of sources (roughly a few hundred). With more than this it can start to take a long time to make the plot! If you provide a header or a list containing the iamge and header to 'header' then it will be plotted with the WCS overlaid using magimageWCS, otherwise it will use magimage.

Value

A data.frame with columns:

segID	Segmentation ID, which can be matched against values in 'segim'
uniqueID	Unique ID, which is fairly static and based on the xmax and ymax position
xcen	Flux weighted x centre
ycen	Flux weighted y centre
xmax	x position of maximum flux
ymax	y position of maximum flux
RAcen	Flux weighted degrees Right Ascension centre (only present if a 'header' is provided)
Deccen	Flux weighted degrees Declination centre (only present if a 'header' is provided)
RAmax	Right Ascension of maximum flux (only present if a 'header' is provided)
Decmax	Declination of maximum flux (only present if a 'header' is provided)
sep	Radial offset between the cen and max definition of the centre (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
flux	Total flux (calculated using 'image'-'sky') in ADUs
mag	Total flux converted to mag using 'magzero'

flux_app	Pseudo aperture (as specified by 'Napp') flux (calculated using 'image'-'sky') in ADUs or Jansky
mag_app	Pseudo aperture (as specified by 'Napp') flux converted to mag using 'magzero'
cenfrac	Fraction of flux in the brightest pixel
N50	Number of brightest pixels containing 50% of the flux
N90	Number of brightest pixels containing 90% of the flux
N100	Total number of pixels in this segment, i.e. contains 100% of the flux
R50	Approximate elliptical semi-major axis containing 50% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
R90	Approximate elliptical semi-major axis containing 90% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
R100	Approximate elliptical semi-major axis containing 100% of the flux (units of 'pixscale', so if 'pixscale' represents the standard asec/pix this will be asec)
SB_N50	Mean surface brightness containing brightest 50% of the flux, calculated as 'flux'*0.5/'N50' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
SB_N90	Mean surface brightness containing brightest 90% of the flux, calculated as 'flux'*0.9/'N90' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
SB_N100	Mean surface brightness containing all of the flux, calculated as 'flux'/'N100' (if 'pixscale' has been set correctly then this column will represent mag/asec^2. Otherwise it will be mag/pix^2)
xsd	Weighted standard deviation in x (always in units of pix)
ysd	Weighted standard deviation in y (always in units of pix)
covxy	Weighted covariance in xy (always in units of pix)
corxy	Weighted correlation in xy (always in units of pix)
con	Concentration, 'R50'/'R90'
asymm	180 degree flux asymmetry (0-1, where 0 is perfect symmetry and 1 complete asymmetry)
flux_reflect	Flux corrected for asymmetry by doubling the contribution of flux for asymmetric pixels (defined as no matching segment pixel found when the segment is rotated through 180 degrees)
mag_reflect	'flux_reflect' converted to mag using 'magzero'
semimaj	Weighted standard deviation along the major axis, i.e. the semi-major first moment, so ~2 times this would be a typical major axis Kron radius (always in units of pix)
semimin	Weighted standard deviation along the minor axis, i.e. the semi-minor first moment, so ~2 times this would be a typical minor axis Kron radius (always in units of pix)
axrat	Axial ratio as given by min/maj
ang	Orientation of the semi-major axis in degrees. This has the convention that 0= | (vertical), 45= \, 90= - (horizontal), 135= /, 180= | (vertical)

signif	Approximate singificance of the detection using the Chi-Square distribution
FPlim	Approximate false-positive significance limit below which one such source might appear spuriously on an image this large
flux_err	Estimated total error in the flux for the segment
mag_err	Estimated total error in the magnitude for the segment
flux_err_sky	Sky subtraction component of the flux error
flux_err_skyRMS	Sky RMS component of the flux error
flux_err_shot	Object shot-noise component of the flux error (only if 'gain' is provided)
flux_err_cor	Error component due to pixel correlation
sky_mean	Mean flux of the sky over all segment pixels
sky_sum	Total flux of the sky over all segment pixels
skyRMS_mean	Mean value of the sky RMS over all segment pixels
Nedge	Number of edge segment pixels that make up the outer edge of the segment
Nsky	Number of edge segment pixels that are touching sky
Nobject	Number of edge segment pixels that are touching another object segment
Nborder	Number of edge segment pixels that are touching the 'image' border
Nmask	Number of edge segment pixels that are touching a masked pixel (note NAs in 'image' are also treated as masked pixels)
edge_frac	Fraction of edge segment pixels that are touching the sky i.e. 'Nsky'/'Nedge', higher generally meaning more robust segmentation statistics
edge_excess	Ratio of the number of edge pixels to the expected number given the elliptical geometry measurements of the segment. If this is larger than 1 then it is a sign that the segment geometry is irregular, and is likely a flag for compromised photometry
flag_border	A binary flag telling the user which 'image' borders the segment touches. The bottom of the 'image' is flagged 1, left=2, top=4 and right=8. A summed combination of these flags indicate the segment is in a corner touching two borders: bottom-left=3, top-left=6, top-right=12, bottom-right=9.

profoundSegimPlot is a simple function that overlays the image segments on the original 'image'. This can be very slow for large numbers (1,000s) of segments because it uses the base contour function to draw the segments individually.

```

`profoundSegimKeep` *Merge Segmentation Map with Grouped Segmentation map*

Description

Allows users to safely merge a standard segim with a groupim, where you can specify segments to be newly merged together, or groups to be merged.

Usage

```
profoundSegimKeep(segim = NULL, groupim = NULL, groupID_merge = NULL, segID_merge = NULL,
clean = FALSE)
```

Arguments

`segim`	Integer matrix; required, the segmentation map.
`groupim`	Integer matrix; the grouped segmentation map. This matrix *must* be the same dimensions as '`segim`' (if supplied).
`groupID_merge`	Integer vector; the group IDs that the user wants to persist into the final segmentation map (removing all '`segim`' segments that overlap with any of the specified group IDs).
`segID_merge`	Integer list; each list element should specify collections of segments to be merged.
`clean`	Logical; should segments partially overlapping with chosen groups be aggressively removed?

Details

The merged segments inherit the lowest segment value, e.g. list(c(1,2,4),c(5,6)) would merge together segments 1,2,4 and to be a new segment 1, and then 5,6 to be a new segment 5.

If the package `fastmatch` is loaded then matching should be faster when multiple groups are being merged together.

Value

Integer matrix; the merged segmentation map, where specified groups and segments have been merged.

## End(Not run)
```

---

profoundSegimMerge *Merge Segmentation Maps*

Description

Takes two segmentation maps and merges them in a sensible manner, making sure segments representing the same object are not overlaid on each other.

Usage

```
profoundSegimMerge(image = NULL, segim_base = NULL, segim_add = NULL, mask = NULL,
sky = 0)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
segim_base	Integer matrix; required, the base segmentation map of the 'image'. This matrix *must* be the same dimensions as 'image'.
segim_add	Integer matrix; required, the new segmentation map of the 'image' that is to be added. This matrix *must* be the same dimensions as 'image'.

mask — Boolean matrix; optional, parts of the image to mask out (i.e. ignore), where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.

sky — User provided estimate of the absolute sky level. Can be a scalar or a matrix matching the dimensions of 'image' (allows values to vary per pixel). This will be subtracted off the 'image' internally, so only provide this if the sky does need to be subtracted!

Details

The merger strategy is quite simple. Matching object segments are identified by the 'uniqueID' ID from an internal run of profoundSegimStats. Whichever segment contains more flux is determined to be the best map to use as the base segment. Unmatched segments in the 'segim_add' map are added back in after this initial merging process, so will end up on top and potentially appear as segment islands within larger segments (which is not possible using the standard segmentation process in profoundMakeSegim).

An obvious reason to use this function is in situations where bright stars are embedded deep within an extended source. The standard watershed segmentation used in profoundMakeSegim will tend to break a large portion of the extended source off to form the segmented region. By running profoundProFound in different modes it is possible to identify the bright peaks (see Examples below), and then use profoundSegimMerge to piece the segments back together appropriately.

Value

Integer matrix; the merged segmentation map matched pixel by pixel to 'image'.

profoundSegimPlot(image, segim=tempmerge)

## End(Not run)
```

`profoundSegimNear` *Segment Neighbour IDs*

Description

Returns a data.frame of all nearby (default is touching) segments surrounding every segment in a provided segim.

Usage

```
profoundSegimNear(segim = NULL, offset = 1)
```

Arguments

`segim`	Integer matrix; a specified segmentation map of the image (required).
`offset`	Integer scalar; the distance to offset when searching for nearby segments.

Details

This function can be run by the user directly, but usually it is called from within a higher routine in the `ProFound` suite of objects detection functions.

Value

A data.frame of lists giving the segIDs of nearby segments for every segment. This is a slightly unusal structure to see in R, but it allows for a compact manner of storing uneven vectors of touching segmentss. E.g. you might have a massive segment touching 30 other segments and many segments touching none. Padding a normal matrix out to accommodate the larger figure would be quite inefficient.

`segID`	Segmentation ID, which can be matched against values in '`segim`'
`nearID`	An embedded list of segmentation IDs for nearby segments. I.e. each list element of '`nearID`' is a vector (see Examples for clarity).
`Nnear`	The total number of segments that are considered to be nearby.

Note

Due to the construction of the segmented curve-of-growth in ProFound you may have cases where the separation between segments is two or three pixels. Since these are very close to touching you might want to catch these close neighbours rather than strictly touching. By increasing '`offset`' to a larger number (2 or 3 in the cases above) you can flag these events.

profoundSegimShare *Calculate Flux Share Matrix*

Description

Given a higher resolution input segmentation map, this function calculates how the original segments are split across a lower resolution segmentation map ('segim_warp'). The output of this will be used to run profoundProFound using a new target segmention map, and the outputs from this photometry run and the 'sharemat' provided will then be passed to profoundShareFlux to create fluxes for sources that are not present in 'segim_warp' but exist in the original 'segim_in'.

Usage

```
profoundSegimShare(segim_in = NULL, header_in = NULL, header_out = NULL, pixcut = 1,
weights = NULL)
```

Arguments

segim_in	Integer matrix; required, the segmentation map we want to remap. If 'segim_in' is a list as created by readFITS, read.fits of magcutoutWCS then the image part of the list is parsed to 'segim_in' and the correct header part is passed to 'header_in'.
header_in	Full FITS header in table or vector format. This should be the header WCS that matches 'segim_in'. Legal table format headers are provided by the read.fitshdr function or the 'hdr' list output of read.fits in the astro package; the 'hdr' output of readFITS in the FITSio package or the 'header' output of magcutoutWCS. If 'header_in' is provided then key words will be taken from here as a priority. Missing header keywords are printed out and other header option arguments are used in these cases.
header_out	Full FITS header in table or vector format. This is the target WCS projection that 'segim_in' will be mapped onto. Legal table format headers are provided by the read.fitshdr function or the 'hdr' list output of read.fits in the astro package; the 'hdr' output of readFITS in the FITSio package or the 'header' output of magcutoutWCS. If 'header_out' is provided then key words will be taken from here as a priority. Missing header keywords are printed out and other header option arguments are used in these cases.
pixcut	Integer scalar; the number of pixels required to identify an object on the new low resolution segmentation map.
weights	Numeric vector; additional weights to modify fluxes by. If provided must be the same length as dim(sharemat)[2] (i.e. the original list of segment properties, not the input 'segstats').

Value

A list containing:

segID_in	Vector, the input segment IDs present in'segim_in'.
segID_warp	Vector, the output segment IDs present in'segim_warp'.
segim_warp	Integer matrix; the remapped image using the target WCS.
sharemat	Numeric matrix; the sharing matrix which will have dimenstion length(segID_warp) x length(segID_in).
shareseg	Numeric vector; the fraction of non-sky 'segim_in' pixels that match the output 'segim_warp', so if near 1 then 'segim_warp' segment should be quite clean of subpixel contaminants.

```

`profoundSegimWarp` *Remap Segmentation Map via Warping*

Description

Remaps an input segmentation map WCS Tan Gnomonic projection system to a different target WCS. This uses `magwarp` with sensible settings, but `magwarp` can be used more directly if the other lower level options are required. This interface should cover most practical use cases though. Using `profoundProFound` with a remapped segmentation map is likely to be more sensible than remapping image flux since it will not produce flux interpolation errors.

Usage

```
profoundSegimWarp(segim_in = NULL, header_in = NULL, header_out = NULL)
```

Arguments

`segim_in`	Integer matrix; required, the segmentation map we want to remap. If '`segim_in`' is a list as created by `readFITS`, `read.fits` of `magcutoutWCS` then the image part of the list is parsed to '`segim_in`' and the correct header part is passed to '`header_in`'.
`header_in`	Full FITS header in table or vector format. This should be the header WCS that matches '`segim_in`'. Legal table format headers are provided by the `read.fitshdr` function or the '`hdr`' list output of `read.fits` in the astro package; the '`hdr`' output of `readFITS` in the `FITSio` package or the '`header`' output of `magcutoutWCS`. If '`header_in`' is provided then key words will be taken from here as a priority. Missing header keywords are printed out and other header option arguments are used in these cases.
`header_out`	Full FITS header in table or vector format. This is the target WCS projection that '`segim_in`' will be mapped onto. Legal table format headers are provided by the `read.fitshdr` function or the '`hdr`' list output of `read.fits` in the astro package; the '`hdr`' output of `readFITS` in the `FITSio` package or the '`header`' output of `magcutoutWCS`. If '`header_out`' is provided then key words will be taken from here as a priority. Missing header keywords are printed out and other header option arguments are used in these cases.

Details

This function uses the '`interpolation`'='nearest' and '`doscale`'=FALSE in `magwarp`.

Value

Integer matrix; the remapped image using the target WCS.

profoundShareFlux *Redistribute Fluxes*

Description

Redistributes fluxes from a lower resolution segmentation map using the 'sharemat' provided by profoundSegimShare.

Usage

```
profoundShareFlux(segstats = NULL, sharemat = NULL, weights = NULL)
```

Arguments

segstats	Data.frame, the profoundProFound 'segstats' output that has been created using the segmentation output by profoundSegimShare.
sharemat	Numeric matrix, the 'sharemat' output that has been created by profoundSegimShare.
weights	Numeric vector; additional weights to modify fluxes by. If provided must be the same length as dim(sharemat)[2] (i.e. the original list of segment properties, not the input 'segstats').

Details

This is a high level utility to extract some useful catalogue properties for objects that have disappeared from the segmentation map when degrading the resolution. Since in this case flux is conserved, we have a few option to decide how to redistribute the flux.

Value

Data.frame with minimal columns. Many properties cannot be redistributed, so we ignore those here. The few which can are flux, flux_err, mag, mag_err, N50, N90, N100 (see profoundSegimStats for a discussion of these properties).

profoundSkyEst *Old Sky Estimator (Somewhat Defunct)*

Description

A high level utility to estimate the sky properties of a supplied 'image'. This is closely related to the equivalent routines available in the LAMBDAR R package.

Usage

```
profoundSkyEst(image = NULL, objects = NULL, mask = NULL, cutlo = cuthi/2,
cuthi = sqrt(sum((dim(image)/2)^2)), skycut = 'auto', clipiters = 5, radweight = 0,
plot = FALSE, ...)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. The galaxy should be approximately central within this image since annuli weighting is done to avoid brighter central regions dominated by galaxy flux.
objects	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as 'image'.
mask	Boolean matrix; optional, non galaxy parts of the image to mask out, where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
cutlo	Numeric scalar; radius where the code will start to calculate the sky annuli around the central object. Should be large enough to avoid significant object flux, i.e. a few times the flux 90 radius. Default is half of 'cuthi'.
cuthi	Numeric scalar; radius where the code will stop calculating the sky annuli around the central object. Default is the corner edge of the 'image'.

skycut	Numeric scalar; clipping threshold to make on the 'image' in units of the skyRMS. The default scales the clipping to the number of pixels in the 'image', and will usually work reasonably.
clipiters	Numeric scalar; How many iterative clips of the sky will be made.
radweight	Numeric scalar; what radius power-law weighting should be used to bias the sky towards sky annuli nearer to the central object. 'radweight'>0 weight the sky value more towards larger radii and 'radweight'<0 weight the sky values towards the 'image' centre. The default of 0 means there is no radial weightings. This becomes clear when plotting the 'radrun' output (see Examples). Note this behaves differently to the similarly named option in LAMBDAR's sky.estimate.
plot	Logical; should a diagnostic plot be generated?
...	Further arguments to be passed to magplot. Only relevant is 'plot'=TRUE.

Details

This function is closely modelled on the sky.estimate function in the LAMBDAR package (the basic elements of which were written by ASGR). The defaults work well for data where the main objects (usually a galaxy) is centrally located in the 'image' since the 'cutlo' default will usually ignore contaminated central pixels. On top of this it does pretty aggressive object pixel rejection using the 'skycut' and 'clipiters' options.

The defaults should work reasonably well on modern survey data (see Examples), but should the solution not be ideal try modifying these parameters (in order of impact priority): 'skycut', 'cutlo', 'radweight', 'clipiters'.

It is interesting to note that a better estimate of the sky RMS can be made by using the output of profoundImDiff (see Examples).

Value

Returns a list with 5 elements:

sky	The value of the estimated sky.
skyerr	The estimated uncertainty in the sky level.
skyRMS	The RMS of the sky pixels.
Nnearsky	The number of sky annuli that have error bars encompassing the final sky.
radrun	The output of magrun for radius versus sky pixels values.

Examples

```
## Not run:
image = readFITS(system.file("extdata", 'KiDS/G266035fitim.fits',
package="ProFit"))$imDat
sky1 = profoundSkyEst(image, plot=TRUE)
image_sky = image-sky1$sky
sky2 = profoundSkyEst(profoundImDiff(image_sky), plot=TRUE)

#You can check whether you are contaminated by the central objects by plotting the radrun
#object in the list (it should be flat for a well behaved sky):
sky = profoundSkyEst(image, cutlo=0, plot=TRUE)
magplot(sky$radrun)
abline(h=sky$sky)

#The above shows heavy contamination by the central object without. We can either mask
#this out using the output of profoundSegImWatershed, set cutlo to be larger or weight
#the sky towards outer annuli.

profound=profoundProFound(image)
sky = profoundSkyEst(image, mask=profound$objects, cutlo=0, plot=TRUE)
magplot(sky$radrun)
abline(h=sky$sky)

#The above is better, but not great. A more aggressive mask helps:

sky = profoundSkyEst(image, mask=profound$objects_redo, cutlo=0, plot=TRUE)
magplot(sky$radrun)
abline(h=sky$sky)

#Or weighting the sky to outer radii

sky = profoundSkyEst(image, mask=profound$objects, cutlo=0, radweight=1, plot=TRUE)
magplot(sky$radrun)
abline(h=sky$sky)

#Finally we can leave the central cutlo mask turned on:

sky = profoundSkyEst(image, mask=profound$objects, plot=TRUE)
magplot(sky$radrun)
abline(h=sky$sky)

## End(Not run)
```

---

profoundSkyEstLoc *Calculate Sky in Subset of Pixels*

Description

Calculate the sky and sky RMS for a subset region of a larger image, as used in profoundMakeSkyMap.

Usage

```
profoundSkyEstLoc(image = NULL, objects = NULL, mask = NULL, loc = dim(image)/2,
box = c(100, 100), skytype = "median", skyRMStype = "quanlo", sigmasel = 1,
skypixmin = prod(box)/2, boxadd = box/2, boxiters = 0, conviters = 100, doclip = TRUE,
shiftloc = FALSE, paddim = TRUE, plot = FALSE, ...)
```

Arguments

image	Numeric matrix; required, the image we want to analyse.
objects	Boolean matrix; optional, object mask where 1 is object and 0 is sky. If provided, this matrix *must* be the same dimensions as 'image'.
mask	Boolean matrix; optional, non galaxy parts of the image to mask out, where 1 means mask out and 0 means use for analysis. If provided, this matrix *must* be the same dimensions as 'image'.
loc	Integer vector; the [x,y] location where we want to estimate the sky and sky RMS.
box	Integer vector; the dimensions of the box car filter to estimate the sky with.
skytype	Character scalar; the type of sky level estimator used. Allowed options are 'median' (the default), 'mean', 'mode' and 'converge' (see Details for an explanation of what these estimators do). In all cases this is the estimator applied to unmasked and non-object pixels. If 'doclip'=TRUE then the pixels will be dynamically sigma clipped before the estimator is run.
skyRMStype	Character scalar; the type of sky level estimator used. Allowed options are 'quanlo' (the default), 'quanhi', 'quanboth', 'sd' and 'converge' (see Details for an explanation of what these estimators do). In all cases this is the estimator applied to unmasked and non-object pixels. If 'doclip'=TRUE then the pixels will be dynamically sigma clipped before the estimator is run.
sigmasel	Numeric scalar; the quantile to use when trying to estimate the true standard-deviation of the sky distribution. If contamination is low then the default of 1 is about optimal in terms of S/N, but you might need to make the value lower when contamination is very high.
skypixmin	Numeric scalar; the minimum number of sky pixels desired in our cutout. The default is that we need half the original number of pixels in the 'box' to be sky.
boxadd	Integer vector; the dimensions to add to the 'box' to capture more pixels if 'skypixmin' has not been achieved.
boxiters	Integer scalar; the number of 'box'+'boxadd' iterations to attempt in order to capture 'skypixmin' sky pixels. The default means the box will not be grown at all.
conviters	Integer scalar; number of iterative sky convergence steps when 'skytype' = 'converge' and/or 'skyRMStype' = 'converge'.
doclip	Logical; should the unmasked non-object pixels used to estimate to local sky value be further sigma-clipped using magclip? Whether this is used or not is a product of the quality of the objects extraction. If all detectable objects really have been found and the dilated objects mask leaves only apparent sky pixels then an advanced user might be confident enough to set this to FALSE. If an doubt, leave as TRUE.

shiftloc	Logical; should the cutout center shift from 'loc' if the desired 'box' size extends beyond the edge of the image? (See magcutout for details).
paddim	Logical; should the cutout be padded with image data until it meets the desired 'box' size (if 'shiftloc' is true) or padded with NAs for data outside the image boundary otherwise? (See magcutout for details).
plot	Logical; should a diagnostic plot be generated?
...	Further arguments to be passed to magimage. Only relevant is 'plot'=TRUE.

Details

This is a somewhat handy standalone utility function if you have a large image and want to check the quality and stability of the local sky and sky RMS.

Regarding 'skytype', the meaning of the 'median' and 'mean' options are obvious enough. The 'mode' is computed by running the data through density with the default options including automatuc selection of the appropriate smoothing band-width. The peak value of the smoothed density is then extracted, and the pixel value at this point is returned as the 'mode' sky estimator. The 'converge' sky uses a convergence scheme based on the estimated mean and variance of a truncated Normal distibution, where it attempts to maximise the likelihood of the population mode and standard deviation for the Normal sky.

Regarding 'skyRMStype', if you know that your contamination only comes from positive flux sources (e.g., astronomical data when trying to select sky pixels) then you should probably use the lower side to determine Normal statistics (quanlo). Similarly if the contamination is on the low side then you should use the higher side to determine Normal statistics (quanhi, but this is rare in astronomical data). If you believe the selected sky pixels to be unbiased then 'quanboth' uses both sides and will give you a more accurate estimator of the sky RMS. The 'sd' option is to use the standard-deviation, with the caveat that this is calculated around the esstimated sky level (of type specified by 'skytype') and not necessarily simply the mean (as it would be typically). The most common choices for 'skyRMStype' will likely be 'quanlo' or 'sd'. The 'converge' sky uses a convergence scheme based on the estimated mean and variance of a truncated Normal distibution, where it attempts to maximise the likelihood of the population mode and standard deviation for the Normal sky.

There are many questions to think about when choosing the best combination of sky estimators. Have all detectable sources been robustly extracted and masked? Is the remaining contamintion due to background undetected sources or wing flux from foreground stars? The most significant choice to be made is whether to choose the more robust 'median' or the potentially biased 'mean'. The former makes sense if you think there might be detectable sources still contributing to your nominal sky pixels, the latter makes sense if the positive flux of undetected sources is spread round the sky in an random but uniform manner. If you are very confident that your object mask represents all plausible sources then you might even want to set 'doclip'=FALSE. The defaults behave in quite a safe manner and have resistance to unmasked objects being included in the sky pixels. Using different options (particularly 'doclip'=FALSE and 'skytype') requires more advanced knowledge about the specific data being anlysed.

If the package Rfast is loaded, then this function will use the faster Rfast::med median function over the base median. This is about a factor 2-3 faster.

Value

A length two vector where the first element is the sky and the second is the skyRMS.

profoundZapSegID *Zap Elements of segID_merge*

Description

This function allows for safe zapping of the 'segID_merge' structure. This is important since it can be tricky to remove elements with logic if you are not an R guru.

Usage

```
profoundZapSegID(segID, segID_merge)
```

Arguments

segID	Integer vector; segment IDs that you want to zap in 'segID_merge'. All list entries that contain any of 'segID' are entirely removed, so this process is very aggressive!
segID_merge	Integer list; each list element should specify collections of segments to be merged.

Details

Zaps unwanted list entries easily.

Value

Output is the zapped version of 'segID_merge':

Integer list; each list element should specify collections of segments to be merged.

(profoundZapSegID(3, example)) #removes first list entry since 3 appears in that vector
(profoundZapSegID(40, example)) #does nothing, since 40 does not appear anywhere
```

---

water_cpp *Rcpp Watershed Function*

Description

This is a standalone implementation of a watershed deblend, with some astronomy specific tweeks. E.g. it is possible to both adapt the extent of the saddlepoint search, and it can be modified by both an absolute and relative tolerance. Defaults behave much like EBImage's watershed function. In general it is a factor of a few faster than the EBImage implementation, especially for large images with lots of deblending required.

Usage

```
water_cpp(image = 0L, nx = 1L, ny = 1L, abstol = 1, reltol = 0, cliptol = 1e+06, ext = 1L,
skycut = 0, pixcut = 1L, verbose = FALSE, Ncheck = 1000000L)
water_cpp_old(image = 0L, nx = 1L, ny = 1L, abstol = 1, reltol = 0, cliptol = 1e+06,
ext = 1L, skycut = 0, pixcut = 1L, verbose = FALSE, Ncheck = 1000000L)
```

Arguments

image	Numeric matrix; required, the image we want to analyse. Note, image NAs are treated as masked pixels.
nx	Integer scalar; required, the dimension x of the supplied 'image', i.e. should be dim(image)[1].
ny	Integer scalar; required, the dimension y of the supplied 'image', i.e. should be dim(image)[2].
abstol	Numeric scalar; the minimum height of the object in the units of image intensity between its highest point (seed) and the point where it contacts another object (checked for every contact pixel). If the height is smaller than the tolerance, the object will be combined with its brightest neighbour. Tolerance should be chosen according to the range of 'image'. Default works well when the 'image' has been divided by the sky-RMS. A larger value of 'abstol' means segments are more aggressively merged together.

reltol	Numeric scalar; a modifier to the 'abstol', modifying it by the ratio of the segment peak flux divided by the saddle point flux to the power 'reltol'. The default means the 'reltol' has no effect since this modifier becomes 1. A larger value of 'reltol' means segments are more aggressively merged together.
cliptol	Numeric scalar; if 'image' is above this level where segments touch then they are always merged, regardless of other criteria. When thinking in terms of sky RMS, values between 20-100 are probably appropriate for merging very bright parts of stars back together in optical data.
ext	Integer scalar; square offset of the neighborhood in pixels for the detection of neighboring objects. Higher value smoothes out small objects.
skycut	Numeric scalar; background value at or under which pixels are not considered anymore for watersheding (so with default 'skycut'=0, 0 valued pixels and below are considered to be part of the sky).
pixcut	Integer scalar; the minimum number of pixels allowed in a segment. Below this number segments are set to 0, i.e. the background. This means they are not considered real objects in profoundProFound.
verbose	Logical; should verbose output be displayed to the user? Since big image can take a long time to run, you might want to monitor progress.
Ncheck	Integer scalar; the pixel scanning interval to check for interupts and for printing out the verbose state.

Details

This was hand written from scratch by A Robotham, but in the end the approach is somewhat similar to EBImage::watershed. There do seem to be fairly large speed improvements for more sparse images though, since only pixels above the background 'skycut' are ever looked at. This knowledge of sparcity does not exist in EBImage::watershed.

water_cpp is the newer variant re-writeen by R Tobar based on the Rcpp implentation. The older Rcpp one is still available as water_cpp_old.

Value

Integer matrix; the segmentation map matched pixel by pixel to 'image'.

Author(s)

Aaron Robotham
