Package 'mboost'

April 26, 2022

Title Model-Based Boosting

Version 2.9-7

Date 2022-04-25

Description Functional gradient descent algorithm
(boosting) for optimizing general risk functions utilizing
component-wise (penalised) least squares estimates or regression
trees as base-learners for fitting generalized linear, additive
and interaction models to potentially high-dimensional data.
Models and algorithms are described in <doi:10.1214/07-STS242>,
a hands-on tutorial is available from <doi:10.1007/s00180-012-0382-5>.
The package allows user-specified loss functions and base-learners.

Depends R (>= 3.2.0), methods, stats, parallel, stabs (>= 0.5-0)

Imports Matrix, survival (>= 3.2-10), splines, lattice, nnls,
quadprog, utils, graphics, grDevices, partykit (>= 1.2-1)

Suggests TH.data, MASS, fields, BayesX, gbm, mlbench, RColorBrewer,
rpart (>= 4.0-3), randomForest, nnet, testthat (>= 0.10.0),
kangar00

License GPL-2

mboost-package   *mboost: Model-Based Boosting*

Description

Functional gradient descent algorithm (boosting) for optimizing general risk functions utilizing
component-wise (penalized) least squares estimates or regression trees as base-learners for fitting
generalized linear, additive and interaction models to potentially high-dimensional data.

Details

This package is intended for modern regression modeling and stands in-between classical gener-
alized linear and additive models, as for example implemented by `lm`, `glm`, or `gam`, and machine-
learning approaches for complex interactions models, most prominently represented by `gbm` and
`randomForest`.

All functionality in this package is based on the generic implementation of the optimization al-
gorithm (function `mboost_fit`) that allows for fitting linear, additive, and interaction models (and
mixtures of those) in low and high dimensions. The response may be numeric, binary, ordered,
censored or count data.

Both theory and applications are discussed by Buehlmann and Hothorn (2007). UseRs with-
out a basic knowledge of boosting methods are asked to read this introduction before analyzing
data using this package. The examples presented in this paper are available as package vignette
`mboost_illustrations`.

Note that the model fitting procedures in this package DO NOT automatically determine an appropriate model complexity. This task is the responsibility of the data analyst.

A description of novel features that were introduced in version 2.0 is given in Hothorn et. al (2010).

Hofner et al. (2014) present a comprehensive hands-on tutorial for using the package mboost, which is also available as vignette(package = "mboost", "mboost_tutorial").

Ben Taieba and Hyndman (2013) used this package for fitting their model in the Kaggle Global Energy Forecasting Competition 2012. The corresponding research paper is a good starting point when you plan to analyze your data using mboost.

NEWS in 2.9-series

Series 2.9 provides a new family (RCG), uses partykit::ctree instead of party::ctree to be more flexible, allows for multivariate negative gradients, and leave-one-out crossvalidation. Further minor changes were introduces and quite some bugs were fixed.

For more details and other changes see
news(Version >= "2.9-0", package = "mboost")

NEWS in 2.8-series

Series 2.8 allows to fit models with zero boosting steps (i.e., models containing only the offset). Furthermore, cross-validation can now also select a model without base-learners. In a Binomial family one can now specifiy links via make.link. With Binomial(type = "glm") an alternative implementation of Binomial models is now existing and defines the model along the lines of the glm implementation. Additionally, it works not only with a two-level factor but also with a two-column matrix containing the number of successes and number of failures. Finally, a new base-learner bkernel for kernel boosting was added. The references were updated and a lot of bugs fixed.

For more details and other changes see
news(Version >= "2.8-0", package = "mboost")

NEWS in 2.7-series

Series 2.7 provides a new family (Cindex), variable importance measures (varimp) and improved plotting facilities. The manual was updated in various places, vignettes were improved and a lot of bugs were fixed.

For more details and other changes see
news(Version >= "2.7-0", package = "mboost")

NEWS in 2.6-series

Series 2.6 includes a lot of bug fixes and improvements. Most notably, the development of the package is now hosted entirely on github in the project boost-R/mboost. Furthermore, the package is now maintained by Benjamin Hofner.

For more details and other changes see
news(Version >= "2.6-0", package = "mboost")

NEWS in 2.5-series

Crossvaliation does not stop on errors in single folds anymore an was sped up by setting `mc.preschedule` = `FALSE` if parallel computations via `mclapply` are used. The `plot.mboost` function is now documented. Values outside the boundary knots are now better handeled (forbidden during fitting, while linear extrapolation is used for prediction). Further perfomance improvements and a lot of bug fixes have been added.

For more details and other changes see
```
news(Version >= "2.5-0",package = "mboost")
```

NEWS in 2.4-series

Bootstrap confidence intervals have been implemented in the novel `confint` function. The stability selection procedure has now been moved to a stand-alone package called **stabs**, which now also implements an iterface to use stability selection with other fitting functions. A generic function for `"mboost"` models is implemented in **mboost**.

For more details and other changes see
```
news(Version >= "2.4-0",package = "mboost")
```

NEWS in 2.3-series

The stability selection procedure has been completely rewritten and improved. The code base is now extensively tested. New options allow for a less conservative error control.

Constrained effects can now be fitted using quadratic programming methods using the option `type = "quad.prog"` (default) for highly improved speed. Additionally, new constraints have been added.

Other important changes include:

- A new replacement function `mstop(mod) <-i` as an alternative to `mod[i]` was added (as suggested by Achim Zeileis).

- We added new families `Hurdle` and `Multinomial`.

- We added a new argument `stopintern` for internal stopping (based on out-of-bag data) during fitting to `boost_control`.

For more details and other changes see
```
news(Version >= "2.3-0",package = "mboost")
```

NEWS in 2.2-series

Starting from version 2.2, the default for the degrees of freedom has changed. Now the degrees of freedom are (per default) defined as

$$\mathrm{df}(\lambda) = \mathrm{trace}(2S - S^\top S),$$

with smoother matrix $S = X(X^\top X + \lambda K)^{-1} X$ (see Hofner et al., 2011). Earlier versions used the trace of the smoother matrix $\mathrm{df}(\lambda) = \mathrm{trace}(S)$ as degrees of freedom. One can change the old definition using `options(mboost_dftraceS = TRUE)` (see also B. Hofner et al., 2011 and `bols`).

Other important changes include:

- We switched from packages `multicore` and `snow` to `parallel`

- We changed the behavior of bols(x,intercept = FALSE) when x is a factor: now the intercept is simply dropped from the design matrix and the coding can be specified as usually for factors. Additionally, a new contrast is introduced: "contr.dummy" (see bols for details).
- We changed the computation of B-spline basis at the boundaries; B-splines now also use equidistant knots in the boundaries (per default).

For more details and other changes see
news(Version >= "2.2-0" & Version < "2.3-0",package = "mboost")

NEWS in 2.1-series

In the 2.1 series, we added multiple new base-learners including bmono (monotonic effects), brad (radial basis functions) and bmrf (Markov random fields), and extended bbs to incorporate cyclic splines (via argument cyclic = TRUE). We also changed the default df for bspatial to 6.

Starting from this version, we now also automatically center the variables in glmboost (argument center = TRUE).

For more details and other changes see
news(Version >= "2.1-0" & Version < "2.2-0",package = "mboost")

NEWS in 2.0-series

Version 2.0 comes with new features, is faster and more accurate in some aspects. In addition, some changes to the user interface were necessary: Subsetting mboost objects changes the object. At each time, a model is associated with a number of boosting iterations which can be changed (increased or decreased) using the subset operator.

The center argument in bols was renamed to intercept. Argument z renamed to by.

The base-learners bns and bss are deprecated and replaced by bbs (which results in qualitatively the same models but is computationally much more attractive).

New features include new families (for example for ordinal regression) and the which argument to the coef and predict methods for selecting interesting base-learners. Predict methods are much faster now.

The memory consumption could be reduced considerably, thanks to sparse matrix technology in package Matrix. Resampling procedures run automatically in parallel on OSes where parallelization via package parallel is available.

The most important advancement is a generic implementation of the optimizer in function mboost_fit.

For more details and other changes see
news(Version >= "2.0-0" & Version < "2.1-0",package = "mboost")

See Also

The main fitting functions include:

- gamboost for boosted (generalized) additive models,
- glmboost for boosted linear models and
- blackboost for boosted trees.

Model tuning is done via cross-validation as implemented in cvrisk.
See there for more details and further links.

Examples

```
data("bodyfat", package = "TH.data")
set.seed(290875)

### model conditional expectation of DEXfat given
model <- mboost(DEXfat ~
    bols(age) +                ### a linear function of age
    btree(hipcirc, waistcirc) + ### a smooth non-linear interaction of
                               ### hip and waist circumference
    bbs(kneebreadth),          ### a smooth function of kneebreadth
    data = bodyfat, control = boost_control(mstop = 100))

### 10-fold cv for assessing `optimal' number of boosting iterations
cvm <- cvrisk(model, papply = lapply,
              folds = cv(model.weights(model), type = "kfold"))
### probably needs larger initial mstop but the
### CRAN team is picky about running times for examples
plot(cvm)
```

```
### restrict model to mstop(cvm)
model[mstop(cvm), return = FALSE]
mstop(model)

### plot age and kneebreadth
layout(matrix(1:2, nc = 2))
plot(model, which = c("age", "kneebreadth"))

### plot interaction of hip and waist circumference
attach(bodyfat)
nd <- expand.grid(hipcirc = h <- seq(from = min(hipcirc),
                                     to = max(hipcirc),
                                     length = 100),
                  waistcirc = w <- seq(from = min(waistcirc),
                                       to = max(waistcirc),
                                       length = 100))
plot(model, which = 2, newdata = nd)
detach(bodyfat)

### customized plot
layout(1)
pr <- predict(model, which = "hip", newdata = nd)
persp(x = h, y = w, z = matrix(pr, nrow = 100, ncol = 100))
```

baselearners	*Base-learners for Gradient Boosting*

Description

Base-learners for fitting base-models in the generic implementation of component-wise gradient boosting in function mboost.

Usage

```
## linear base-learner
bols(..., by = NULL, index = NULL, intercept = TRUE, df = NULL,
     lambda = 0, contrasts.arg = "contr.treatment")

## smooth P-spline base-learner
bbs(..., by = NULL, index = NULL, knots = 20, boundary.knots = NULL,
    degree = 3, differences = 2, df = 4, lambda = NULL, center = FALSE,
    cyclic = FALSE, constraint = c("none", "increasing", "decreasing"),
    deriv = 0)

## bivariate P-spline base-learner
bspatial(..., df = 6)

## radial basis functions base-learner
```

```
brad(..., by = NULL, index = NULL, knots = 100, df = 4, lambda = NULL,
     covFun = fields::stationary.cov,
     args = list(Covariance="Matern", smoothness = 1.5, theta=NULL))

## (genetic) pathway-based kernel base-learner
bkernel(..., df = 4, lambda = NULL, kernel = c("lin", "sia", "net"),
        pathway = NULL, knots = NULL, args = list())

## random effects base-learner
brandom(..., by = NULL, index = NULL, df = 4, lambda = NULL,
        contrasts.arg = "contr.dummy")

## tree based base-learner
btree(..., by = NULL, nmax = Inf, tree_controls = partykit::ctree_control(
    teststat = "quad", testtype = "Teststatistic",
    mincriterion = 0, minsplit = 10, minbucket = 4,
    maxdepth = 1, saveinfo = FALSE))

## constrained effects base-learner
bmono(...,
      constraint = c("increasing", "decreasing", "convex", "concave",
                     "none", "positive", "negative"),
      type = c("quad.prog", "iterative"),
      by = NULL, index = NULL, knots = 20, boundary.knots = NULL,
      degree = 3, differences = 2, df = 4, lambda = NULL,
      lambda2 = 1e6, niter=10, intercept = TRUE,
      contrasts.arg = "contr.treatment",
      boundary.constraints = FALSE,
      cons.arg = list(lambda = 1e+06, n = NULL, diff_order = NULL))

## Markov random field base-learner
bmrf(..., by = NULL, index = NULL, bnd = NULL, df = 4, lambda = NULL,
     center = FALSE)

## user-specified base-learner
buser(X, K = NULL, by = NULL, index = NULL, df = 4, lambda = NULL)

## combining single base-learners to form new,
## more complex base-learners
bl1 %+% bl2
bl1 %X% bl2
bl1 %O% bl2
```

Arguments

...	one or more predictor variables or one matrix or data frame of predictor variables. For smooth base-learners, the number of predictor variables and the number of columns in the data frame / matrix must be less than or equal to 2. If a matrix (with at least 2 columns) is given to bols or brandom, it is directly

used as the design matrix. Especially, no intercept term is added regardless of argument `intercept`. If the argument has only one column, it is simplified to a vector and an intercept is added or not according to the argmuent `intercept`.

by   an optional variable defining varying coefficients, either a factor or numeric variable. If by is a factor, the coding is determined by the global `options("contrasts")` or as specified "locally" for the factor (see [contrasts](#)). Per default treatment coding is used. Note that the main effect needs to be specified in a separate base-learner. `btree` currently only allows binary factors.

index   a vector of integers for expanding the variables in `...`. For example, `bols(x,index = index)` is equal to `bols(x[index])`, where `index` is an integer of length greater or equal to `length(x)`.

df   trace of the hat matrix for the base-learner defining the base-learner complexity. Low values of `df` correspond to a large amount of smoothing and thus to "weaker" base-learners. Certain restrictions have to be kept for the specification of `df` since most of the base-learners rely on penalization approaches with a non-trivial null space. For example, for P-splines fitted with `bbs`, `df` has to be larger than the order of differences employed in the construction of the penalty term. However, when option `center != FALSE`, the effect is centered around its unpenalized part and therefore any positive number is admissible for `df`. For details on the computation of degrees of freedom see section 'Global Options'.

lambda   smoothing penalty, computed from `df` when `df` is specified. For details on the computation of degrees of freedom see section 'Global Options'.

knots   either the number of knots or a vector of the positions of the interior knots (for more details see below). For multiple predictor variables, `knots` may be a named list where the names in the list are the variable names.

boundary.knots   boundary points at which to anchor the B-spline basis (default the range of the data). A vector (of length 2) for the lower and the upper boundary knot can be specified.This is only advised for `bbs(...,cyclic = TRUE)`, where the boundary knots specify the points at which the cyclic function should be joined. In analogy to `knots` a names list can be specified.

degree   degree of the regression spline.

differences   a non-negative integer, typically 1, 2 or 3. If `differences = k`, k-th-order differences are used as a penalty (*0*-th order differences specify a ridge penalty).

intercept   if `intercept = TRUE` an intercept is added to the design matrix of a linear base-learner. If `intercept = FALSE`, continuous covariates should be (mean-) centered.

center   if `center != FALSE` the corresponding effect is re-parameterized such that the unpenalized part of the fit is subtracted and only the deviation effect is fitted. The unpenalized, parametric part has then to be included in separate base-learners using `bols` (see the examples below). There are two possible ways to re-parameterization; `center = "differenceMatrix"` is based on the difference matrix (the default for bbs with one covariate only) and `center = "spectralDecomp"` uses a spectral decomposition of the penalty matrix (see Fahrmeir et al., 2004, Section 2.3 for details). The latter option is the default (and currently only option) for bbs with multiple covariates or `bmrf`.

cyclic	if `cyclic = TRUE` the fitted values coincide at the boundaries (useful for cyclic covariates such as day time etc.). For details see Hofner et al. (2016).
covFun	the covariance function (i.e. radial basis) needed to compute the basis functions. Per default `stationary.cov` function (from package `fields`) is used.
args	a named list of arguments to be passed to `cov.function`. Thus strongly dependent on the specified `cov.function`.
kernel	one of `"lin"` (linear kernel), `"sia"` (size adjusted kernel), or `"net"` (network kernel). For details see `calc_kernel`
pathway	name of pathway; Pathway needs to be contained in the GWAS data set.
contrasts.arg	a named list of characters suitable for input to the `contrasts` replacement function, or the contrast matrix itself, see `model.matrix`, or a single character string (or contrast matrix) which is then used as contrasts for all factors in this base-learner (with the exception of factors in by). See also example below for setting contrasts. Note that a special `contrasts.arg` exists in package mboost, namely "contr.dummy". This contrast is used per default in `brandom` and can also be used in `bols`. It leads to a dummy coding as returned by `model.matrix(~ x -1)` were the intercept is implicitly included but each factor level gets a seperate effect estimate (see example below).
nmax	integer, maximal number of bins in the predictor variables. Use `Inf` to switch-off binning.
tree_controls	an object of class `"TreeControl"`, which can be obtained using `ctree_control`. Defines hyper-parameters for the trees which are used as base-learners, stumps are fitted by default. By default, stumps and thus additive models are fitted.
constraint	type of constraint to be used. For bmono, the constraint can be either monotonic `"increasing"` (default), `"decreasing"`, or `"convex"` or `"concave"`. Additionally, `"none"` can be used to specify unconstrained P-splines. This is especially of interest in conjunction with `boundary.constraints = TRUE`. For bbs, the constraint can be `"none"`, monotonic `"increasing"`, or `"decreasing"`. In general it is advisable to use bmono to fit monotonic splines.
type	determines how the constrained least squares problem should be solved. If `type = "quad.prog"`, a numeric quadratic programming method (Goldfarb and Idnani, 1982, 1983) is used (see `solve.QP` in package **quadprog**). If `type = "iterative"`, the iterative procedure described in Hofner et al. (2011b) is used. The quadratic programming approach is usually much faster than the iterative approach. For details see Hofner et al. (2016).
lambda2	penalty parameter for the (monotonicity) constraint.
niter	maximum number of iterations used to compute constraint estimates. Increase this number if a warning is displayed.
boundary.constraints	
	a logical indicating whether additional constraints on the boundaries of the spline should be applied (default: FALSE). This is still experimental.
cons.arg	a named list with additional arguments for boundary constraints. The element `lambda` specifies the penalty parameter that is used for the additional boundary constraint. The element n specifies the number of knots to be subject to the constraint and can be either a scalar (use same number of constrained knots on

	each side) or a vector. Per default 10% of the knots on each side are used. The element diff_order can be used to specify the order of the boundary penalty: 1 (constant; default for monotonically constrained effects) or 2 (linear; default for all other effects).
bnd	Object of class bnd, in which the boundaries of a map are defined and from which neighborhood relations can be constructed. See [read.bnd]. If a boundary object is not available, the neighborhood matrix can also be given directly.
X	design matrix as it should be used in the penalized least squares estimation. Effect modifiers do not need to be included here (by can be used for convenience).
K	penalty matrix as it should be used in the penalized least squares estimation. If NULL (default), unpenalized estimation is used.
deriv	an integer; the derivative of the spline of the given order at the data is computed, defaults to zero. Note that this argument is only used to set up the design matrix and cannot be used in the fitting process.
bl1	a linear base-learner or a list of linear base-learners.
bl2	a linear base-learner or a list of linear base-learners.

Details

bols refers to linear base-learners (potentially estimated with a ridge penalty), while bbs provide penalized regression splines. bspatial fits bivariate surfaces and brandom defines random effects base-learners. In combination with option by, these base-learners can be turned into varying coefficient terms. The linear base-learners are fitted using Ridge Regression where the penalty parameter lambda is either computed from df (default for bbs, bspatial, and brandom) or specified directly (lambda = 0 means no penalization as default for bols).

In bols(x), x may be a numeric vector or factor. Alternatively, x can be a data frame containing numeric or factor variables. In this case, or when multiple predictor variables are specified, e.g., using bols(x1,x2), the model is equivalent to lm(y ~ .,data = x) or lm(y ~ x1 + x2), respectively. By default, an intercept term is added to the corresponding design matrix (which can be omitted using intercept = FALSE). It is *strongly* advised to (mean-) center continuous covariates, if no intercept is used in bols (see Hofner et al., 2011a). If x is a matrix, it is directly used as the design matrix and no further preprocessing (such as addition of an intercept) is conducted. When df (or lambda) is given, a ridge estimator with df degrees of freedom (see section 'Global Options') is used as base-learner. Note that all variables are treated as a group, i.e., they enter the model together if the corresponding base-learner is selected. For ordinal variables, a ridge penalty for the differences of the adjacent categories (Gertheiss and Tutz 2009, Hofner et al. 2011a) is applied.

With bbs, the P-spline approach of Eilers and Marx (1996) is used. P-splines use a squared *k*-th-order difference penalty which can be interpreted as an approximation of the integrated squared *k*-th derivative of the spline. In bbs the argument knots specifies either the number of (equidistant) *interior* knots to be used for the regression spline fit or a vector including the positions of the *interior* knots. Additionally, boundary.knots can be specified. However, this is only advised if one uses cyclic constraints, where the boundary.knots specify the points where the function is joined (e.g., boundary.knots = c(0,2 * pi) for angles as in a sine function or boundary.knots = c(0,24) for hours during the day). For details on cylcic splines in the context of boosting see Hofner et al. (2016).

bspatial implements bivariate tensor product P-splines for the estimation of either spatial effects or interaction surfaces. Note that bspatial(x,y) is equivalent to bbs(x,y,df = 6). For possible

arguments and defaults see there. The penalty term is constructed based on bivariate extensions of the univariate penalties in x and y directions, see Kneib, Hothorn and Tutz (2009) for details. Note that the dimensions of the penalty matrix increase (quickly) with the number of knots with strong impact on computational time. Thus, both should not be chosen to large. Different knots for x and y can be specified by a named list.

brandom(x) specifies a random effects base-learner based on a factor variable x that defines the grouping structure of the data set. For each level of x, a separate random intercept is fitted, where the random effects variance is governed by the specification of the degrees of freedom df or lambda (see section 'Global Options'). Note that brandom(...) is essentially a wrapper to bols(...,df = 4,contrasts.arg = "contr.dummy"), i.e., a wrapper that utilizes ridge-penalized categorical effects. For possible arguments and defaults see bols.

For all linear base-learners the amount of smoothing is determined by the trace of the hat matrix, as indicated by df.

If by is specified as an additional argument, a varying coefficients term is estimated, where by is the interaction variable and the effect modifier is given by either x or x and y (specified via ...). If bbs is used, this corresponds to the classical situation of varying coefficients, where the effect of by varies over the co-domain of x. In case of bspatial as base-learner, the effect of by varies with respect to both x and y, i.e. an interaction surface between x and y is specified as effect modifier. For brandom specification of by leads to the estimation of random slopes for covariate by with grouping structure defined by factor x instead of a simple random intercept. In bbs, bspatial and brandom the computation of the smoothing parameter lambda for given df, or vice versa, might become (numerically) instable if the values of the interaction variable by become too large. In this case, we recommend to rescale the interaction covariate e.g. by dividing by max(abs(by)). If bbs or bspatial is specified with an factor variable by with more than two factors, the degrees of freedom are shared for the complete base-learner (i.e., spread over all factor levels). Note that the null space (see next paragraph) increases, as a separate null space for each factor level is present. Thus, the minimum degrees of freedom increase with increasing number of levels of by (if center = FALSE).

For bbs and bspatial, option center != FALSE requests that the fitted effect is centered around its parametric, unpenalized part (the so called null space). For example, with second order difference penalty, a linear effect of x remains unpenalized by bbs and therefore the degrees of freedom for the base-learner have to be larger than two. To avoid this restriction, option center = TRUE subtracts the unpenalized linear effect from the fit, allowing to specify any positive number as df. Note that in this case the linear effect x should generally be specified as an additional base-learner bols(x). For bspatial and, for example, second order differences, a linear effect of x (bols(x)), a linear effect of y (bols(y)), and their interaction (bols(x*y)) are subtracted from the effect and have to be added separately to the model equation. More details on centering can be found in Kneib, Hothorn and Tutz (2009) and Fahrmeir, Kneib and Lang (2004). We strongly recommend to consult the latter reference before using this option.

brad(x) specifies penalized radial basis functions as used in Kriging. If knots is used to specify the number of knots, the function cover.design is used to specify the location of the knots such that they minimize a geometric space-filling criterion. Furthermore, knots can be specified directly via a matrix. The cov.function allows to specify the radial basis functions. Per default, the flexible Matern correlation function is used. This is specified using cov.function = stationary.cov with Covariance = "Matern" specified via args. If an effective range theta is applicable for the correlation function (e.g., the Matern family) the user can specify this value. Per default (if theta = NULL) the effective range is chosen as $\theta = max(||x_i - x_j||)/c$ such that the correlation function

$$\rho(c; \theta = 1) = \varepsilon,$$

where $\varepsilon = 0.001$.

bmrf builds a base of a Markov random field consisting of several regions with a neighborhood structure. The input variable is the observed region. The penalty matrix is either construed from a boundary object or must be given directly via the option bnd. In that case the dimnames of the matrix have to be the region names, on the diagonal the number of neighbors have to be given for each region, and for each neighborhood relation the value in the matrix has to be -1, else 0. With a boundary object at hand, the fitted or predicted values can be directly plotted into the map using drawmap.

bkernel can be used to fit linear (kernel = "lin"), size-adjusted (kernel = "sia") or network (kernel = "net") kernels based on genetic pathways for genome-wide assosiation studies. For details see Friedrichs et al. (2017) and check the associated package **kangar00**.

buser(X,K) specifies a base-learner with user-specified design matrix X and penalty matrix K, where X and K are used to minimize a (penalized) least squares criterion with quadratic penalty. This can be used to easily specify base-learners that are not implemented (yet). See examples below for details how buser can be used to mimic existing base-learners. Note that for predictions you need to set up the design matrix for the new data manually.

For a categorical covariate with non-observed categories bols(x) and brandom(x) both assign a zero effect to these categories. However, the non-observed categories must be listed in levels(x). Thus, predictions are possible for new observations if they correspond to this category.

By default, all linear base-learners include an intercept term (which can be removed using intercept = FALSE for bols). In this case, the respective covariate should be mean centered (if continuous) and an explicit global intercept term should be added to gamboost via bols (see example below). With bols(x,intercept = FALSE) with categorical covariate x a separate effect for each group (mean effect) is estimated (see examples for resulting design matrices).

Smooth estimates with constraints can be computed using the base-learner bmono() which specifies P-spline base-learners with an additional asymmetric penalty enforcing monotonicity or convexity/concavity (see and Eilers, 2005). For more details in the boosting context and monotonic effects of ordinal factors see Hofner, Mueller and Hothorn (2011b). The quadratic-programming based algorithm is described in Hofner et al. (2016). Alternative monotonicity constraints are implemented via T-splines in bbs() (Beliakov, 2000). In general it is advisable to use bmono to fit monotonic splines as T-splines show undesirable behaviour if the observed data deviates from monotonicty.

Two or more linear base-learners can be joined using %+%. A tensor product of two or more linear base-learners is returned by %X%. When the design matrix can be written as the Kronecker product of two matrices X = kronecker(X2,X1), then bl1 %O% bl2 with design matrices X1 and X2, respectively, can be used to efficiently compute Ridge-estimates following Currie, Durban, Eilers (2006). In all cases the overall degrees of freedom of the combined base-learner increase (additive or multiplicative, respectively). These three features are experimental and for expert use only.

btree fits a stump to one or more variables. Note that blackboost is more efficient for boosting stumps. For further references see Hothorn, Hornik, Zeileis (2006) and Hothorn et al. (2010).

Note that the base-learners bns and bss are deprecated (and no longer available). Please use bbs instead, which results in qualitatively the same models but is computationally much more attractive.

Value

An object of class blg (base-learner generator) with a dpp function.

The call of dpp returns an object of class bl (base-learner) with a `fit` function. The call to `fit` finally returns an object of class bm (base-model).

Global Options

Three global options affect the base-learners:

options("mboost_useMatrix") defaulting to TRUE indicates that the base-learner may use sparse matrix techniques for its computations. This reduces the memory consumption but might (for smaller sample sizes) require more computing time.

options("mboost_indexmin") is an integer that specifies the minimum sample size needed to optimize model fitting by automatically taking ties into account (default = 10000).

options("mboost_dftraceS") FALSE by default, indicating how the degrees of freedom should be computed. Per default

$$\mathrm{df}(\lambda) = \mathrm{trace}(2S - S^\top S),$$

with smoother matrix $S = X(X^\top X + \lambda K)^{-1}X$ is used (see Hofner et al., 2011a). If TRUE, the trace of the smoother matrix $\mathrm{df}(\lambda) = \mathrm{trace}(S)$ is used as degrees of freedom.

Note that these formulae specify the relation of df and lambda as the smoother matrix S depends only on λ (and the (fixed) design matrix X, the (fixed) penalty matrix K).

blackboost   *Gradient Boosting with Regression Trees*

Description

Gradient boosting for optimizing arbitrary loss functions where regression trees are utilized as base-learners.

Usage

```
blackboost(formula, data = list(),
           weights = NULL, na.action = na.pass,
           offset = NULL, family = Gaussian(),
           control = boost_control(),
           oobweights = NULL,
           tree_controls = partykit::ctree_control(
               teststat = "quad",
               testtype = "Teststatistic",
               mincriterion = 0,
               minsplit = 10,
               minbucket = 4,
               maxdepth = 2,
               saveinfo = FALSE),
          ...)
```

Arguments

formula	a symbolic description of the model to be fit.
data	a data frame containing the variables in the model.
weights	an optional vector of weights to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs.
offset	a numeric vector to be used as offset (optional).
family	a [Family](#) object.
control	a list of parameters controlling the algorithm. For more details see [boost_control](#).
oobweights	an additional vector of out-of-bag weights, which is used for the out-of-bag risk (i.e., if boost_control(risk = "oobag")). This argument is also used internally by cvrisk.
tree_controls	an object of class "TreeControl", which can be obtained using [ctree_control](#). Defines hyper-parameters for the trees which are used as base-learners. It is wise to make sure to understand the consequences of altering any of its arguments. By default, two-way interactions (but not deeper trees) are fitted.
...	additional arguments passed to [mboost_fit](#), including weights, offset, family and control. For default values see [mboost_fit](#).

Details

This function implements the 'classical' gradient boosting utilizing regression trees as base-learners. Essentially, the same algorithm is implemented in package [gbm](#). The main difference is that arbitrary loss functions to be optimized can be specified via the family argument to blackboost whereas

gbm uses hard-coded loss functions. Moreover, the base-learners (conditional inference trees, see ctree) are a little bit more flexible.

The regression fit is a black box prediction machine and thus hardly interpretable.

Partial dependency plots are not yet available; see example section for plotting of additive tree models.

Value

An object of class mboost with print and predict methods being available.

Examples

```
### a simple two-dimensional example: cars data
cars.gb <- blackboost(dist ~ speed, data = cars,
                      control = boost_control(mstop = 50))
cars.gb

### plot fit
plot(dist ~ speed, data = cars)
lines(cars$speed, predict(cars.gb), col = "red")

### set up and plot additive tree model
if (require("partykit")) {
    ctrl <- ctree_control(maxdepth = 3)
    viris <- subset(iris, Species != "setosa")
    viris$Species <- viris$Species[, drop = TRUE]
    imod <- mboost(Species ~ btree(Sepal.Length, tree_controls = ctrl) +
```

```
                            btree(Sepal.Width, tree_controls = ctrl) +
                            btree(Petal.Length, tree_controls = ctrl) +
                            btree(Petal.Width, tree_controls = ctrl),
                    data = viris, family = Binomial())[500]
    layout(matrix(1:4, ncol = 2))
    plot(imod)
}
```

---

boost_control   *Control Hyper-parameters for Boosting Algorithms*

Description

Definition of the initial number of boosting iterations, step size and other hyper-parameters for boosting algorithms.

Usage

```
boost_control(mstop = 100, nu = 0.1,
              risk = c("inbag", "oobag", "none"), stopintern = FALSE,
              center = TRUE, trace = FALSE)
```

Arguments

mstop	an integer giving the number of initial boosting iterations. If mstop = 0, the offset model is returned.
nu	a double (between 0 and 1) defining the step size or shrinkage parameter. The default is probably too large for many applications with family = Poisson() and a smaller value is better.
risk	a character indicating how the empirical risk should be computed for each boosting iteration. inbag leads to risks computed for the learning sample (i.e., all non-zero weights), oobag to risks based on the out-of-bag (all observations with zero weights) and none to no risk computations at all.
stopintern	a logical that defines if the boosting algorithm stops internally when the out-of-bag risk in one iteration is larger than the out-of-bag risk in the iteration before. Can also be a positive number giving the risk difference that needs to be exceeded.
center	deprecated. A logical indicating if the numerical covariates should be mean centered before fitting. Only implemented for [glmboost](). In [blackboost]() centering is not needed. In [gamboost]() centering is only needed if [bols]() base-learners are specified without intercept. In this case centering of the covariates is essential and should be done manually (at the moment). Will be removed in favour of a corresponding argument in glmboost in the future (and gives a warning).
trace	a logical triggering printout of status information during the fitting process.

Details

Objects returned by this function specify hyper-parameters of the boosting algorithms implemented in glmboost, gamboost and blackboost (via the control argument).

Value

An object of class boost_control, a list.

boost_family-class   *Class "boost_family": Gradient Boosting Family*

Description

Objects of class boost_family define negative gradients of loss functions to be optimized.

Objects from the Class

Objects can be created by calls of the form Family(...)

Slots

ngradient: a function with arguments y and f implementing the *negative* gradient of the loss function.

risk: a risk function with arguments y, f and w, the weighted mean of the loss function by default.

offset: a function with argument y and w (weights) for computing a *scalar* offset.

weights: a logical indicating if weights are allowed.

check_y: a function for checking the class / mode of a response variable.

nuisance: a function for extracting nuisance parameters.

response: inverse link function of a GLM or any other transformation on the scale of the response.

rclass: function to derive class predictions from conditional class probabilities (for models with factor response variable).

name: a character giving the name of the loss function for pretty printing.

charloss: a character, the deparsed loss function.

confint.mboost   *Pointwise Bootstrap Confidence Intervals*

Description

Compute and display pointwise confidence intervals

Usage

```
## S3 method for class 'mboost'
confint(object, parm = NULL, level = 0.95, B = 1000,
        B.mstop = 25, newdata = NULL, which = parm,
        papply = ifelse(B.mstop == 0, mclapply, lapply),
        cvrisk_options = list(), ...)
## S3 method for class 'mboost.ci'
plot(x, which, level = x$level, ylim = NULL, type = "l", col = "black",
    ci.col = rgb(170, 170, 170, alpha = 85, maxColorValue = 255),
    raw = FALSE, print_levelplot = TRUE,...)
## S3 method for class 'mboost.ci'
lines(x, which, level = x$level,
    col = rgb(170, 170, 170, alpha = 85, maxColorValue = 255),
    raw = FALSE, ...)

## S3 method for class 'glmboost'
confint(object, parm = NULL, level = 0.95,
        B = 1000, B.mstop = 25, which = parm, ...)
## S3 method for class 'glmboost.ci'
print(x, which = NULL, level = x$level, pe = FALSE, ...)
```

Arguments

object   a fitted model object of class glmboost, gamboost or mboost for which the
                  confidence intervals should be computed.

parm, which   a subset of base-learners to take into account for computing confidence intervals.
                  See mboost_methods for details. parm is just a synonyme for which to be in line
                  with the generic confint function. Preferably use which.

level   the confidence level required.

B   number of outer bootstrap replicates used to compute the empirical bootstrap
                  confidence intervals.

B.mstop   number of inner bootstrap replicates used to determine the optimal mstop on
                  each of the B bootstrap samples.

newdata   optionally, a data frame on which to compute the predictions for the confidence
                  intervals.

papply	(parallel) apply function for the outer bootstrap, defaults to mclapply if no inner bootstrap is used to determine the optimal stopping iteration. For details see argument papply in cvrisk. Be careful with your computing resources if you use parallel computing for both, the inner and the outer bootstrap.
cvrisk_options	(optionally) specify a named list with arguments to the inner bootstrap. For example use cvrisk_options = list(mc.cores = 2) to specify that the mclapply function within cvrisk uses 2 cores to compute the optimal mstop.
x	a confidence interval object.
ylim	limits of the y scale. Per default computed from the data to plot.
type	type of graphic for the point estimate, i.e., for the predicted function. Per default a line is plotted.
col	color of the point estimate, i.e., for the predicted function.
ci.col	color of the confidence interval.
raw	logical, should the raw function estimates or the derived confidence estimates be plotted?
print_levelplot	
	logical, should the **lattice** levelplot be printed or simply returned for further modifications. This argument is only considered if bivariate effect estimates are plotted. If print_levelplot is set to FALSE, a list with objects mean, lowerPI and upperPI is returned containing the three levelplot objects.
pe	logical, should the point estimtate (PE) be also returned?
...	additional arguments to the outer bootstrap such as mc.cores.

Details

Use a nested boostrap approach to compute pointwise confidence intervals for the predicted partial functions or regression parameters. The approach is further described in Hofner et al. (2016).

Value

An object of class glmboost.ci or mboost.ci with special print and/or plot functions.

cvrisk   *Cross-Validation*

Description

Cross-validated estimation of the empirical risk for hyper-parameter selection.

Usage

```
## S3 method for class 'mboost'
cvrisk(object, folds = cv(model.weights(object)),
       grid = 0:mstop(object),
       papply = mclapply,
       fun = NULL, mc.preschedule = FALSE, ...)
cv(weights, type = c("bootstrap", "kfold", "subsampling"),
   B = ifelse(type == "kfold", 10, 25), prob = 0.5, strata = NULL)

## Plot cross-valiation results
## S3 method for class 'cvrisk'
plot(x,
     xlab = "Number of boosting iterations", ylab = attr(x, "risk"),
     ylim = range(x), main = attr(x, "type"), ...)
```

Arguments

object	an object of class mboost.
folds	a weight matrix with number of rows equal to the number of observations. The number of columns corresponds to the number of cross-validation runs. Can be computed using function cv and defaults to 25 bootstrap samples.
grid	a vector of stopping parameters the empirical risk is to be evaluated for.
papply	(parallel) apply function, defaults to mclapply. Alternatively, parLapply can be used. In the latter case, usually more setup is needed (see example for some details). To run cvrisk sequentially (i.e. not in parallel), one can use lapply.
fun	if fun is NULL, the out-of-sample risk is returned. fun, as a function of object, may extract any other characteristic of the cross-validated models. These are returned as is.
mc.preschedule	preschedule tasks if are parallelized using mclapply (default: FALSE)? For details see mclapply.
weights	a numeric vector of weights for the model to be cross-validated.
type	character argument for specifying the cross-validation method. Currently (stratified) bootstrap, k-fold cross-validation and subsampling are implemented.
B	number of folds, per default 25 for bootstrap and subsampling and 10 for kfold.
prob	percentage of observations to be included in the learning samples for subsampling.
strata	a factor of the same length as weights for stratification.
x	an object of class cvrisk.
xlab, ylab	axis labels.

ylim	limits of y-axis.
main	main title of graphic.
...	additional arguments passed to mclapply or plot.

Details

The number of boosting iterations is a hyper-parameter of the boosting algorithms implemented in this package. Honest, i.e., cross-validated, estimates of the empirical risk for different stopping parameters mstop are computed by this function which can be utilized to choose an appropriate number of boosting iterations to be applied.

Different forms of cross-validation can be applied, for example 10-fold cross-validation or bootstrapping. The weights (zero weights correspond to test cases) are defined via the folds matrix.

cvrisk runs in parallel on OSes where forking is possible (i.e., not on Windows) and multiple cores/processors are available. The scheduling can be changed by the corresponding arguments of mclapply (via the dot arguments).

The function cv can be used to build an appropriate weight matrix to be used with cvrisk. If strata is defined sampling is performed in each stratum separately thus preserving the distribution of the strata variable in each fold.

There exist various functions to display and work with cross-validation results. One can print and plot (see above) results and extract the optimal iteration via mstop.

Value

An object of class cvrisk (when fun wasn't specified), basically a matrix containing estimates of the empirical risk for a varying number of bootstrap iterations. plot and print methods are available as well as a mstop method.

Family   *Gradient Boosting Families*

Description

boost_family objects provide a convenient way to specify loss functions and corresponding risk
functions to be optimized by one of the boosting algorithms implemented in this package.

Usage

```
Family(ngradient, loss = NULL, risk = NULL,
       offset = function(y, w)
           optimize(risk, interval = range(y),
                     y = y, w = w)$minimum,
       check_y = function(y) y,
       weights = c("any", "none", "zeroone", "case"),
       nuisance = function() return(NA),
       name = "user-specified", fW = NULL,
       response = function(f) NA,
       rclass = function(f) NA)
AdaExp()
AUC()
Binomial(type = c("adaboost", "glm"),
         link = c("logit", "probit", "cloglog", "cauchit", "log"), ...)
GaussClass()
```

```
GaussReg()
Gaussian()
Huber(d = NULL)
Laplace()
Poisson()
GammaReg(nuirange = c(0, 100))
CoxPH()
QuantReg(tau = 0.5, qoffset = 0.5)
ExpectReg(tau = 0.5)
NBinomial(nuirange = c(0, 100))
PropOdds(nuirange = c(-0.5, -1), offrange = c(-5, 5))
Weibull(nuirange = c(0, 100))
Loglog(nuirange = c(0, 100))
Lognormal(nuirange = c(0, 100))
Gehan()
Hurdle(nuirange = c(0, 100))
Multinomial()
Cindex(sigma = 0.1, ipcw = 1)
RCG(nuirange = c(0, 1), offrange = c(-5, 5))
```

Arguments

ngradient	a function with arguments y, f and w implementing the *negative* gradient of the loss function (which is to be minimized).
loss	an optional loss function with arguments y and f.
risk	an optional risk function with arguments y, f and w to be minimized (!), the weighted mean of the loss function by default.
offset	a function with argument y and w (weights) for computing a *scalar* offset.
fW	transformation of the fit for the diagonal weights matrix for an approximation of the boosting hat matrix for loss functions other than squared error.
response	inverse link function of a GLM or any other transformation on the scale of the response.
rclass	function to derive class predictions from conditional class probabilities (for models with factor response variable).
check_y	a function for checking and transforming the class / mode of a response variable.
nuisance	a function for extracting nuisance parameters from the family.
weights	a character indicating what type of weights are allowed. These can be either arbitrary (non-negative) weights code"any", only zero and one weights "zeroone", (non-negative) interger weights "case", or no weights are allowed "none".
name	a character giving the name of the loss function for pretty printing.
type	which parameterization of Binomial shoule be used?b
link	link function. For possible values see Usage section.
d	delta parameter for Huber loss function. If omitted, it is chosen adaptively.
tau	the quantile or expectile to be estimated, a number strictly between 0 and 1.

qoffset	quantile of response distribution to be used as offset, i.e., starting values for the intercept. Per default the median of the response is used, which is in general a good choice (see Fenske et al. 2011, for details).
nuirange	a vector containing the end-points of the interval to be searched for the minimum risk w.r.t. the nuisance parameter. In case of PropOdds, the starting values for the nuisance parameters.
offrange	interval to search in for offset.
sigma	smoothness parameter for sigmoid functions inside Cindex.
ipcw	vector containing inverse probability of censoring weights for all observations. If omitted, it is estimated inside Cindex family.
...	additional arguments to link functions.

Details

The boosting algorithm implemented in [mboost](#) minimizes the (weighted) empirical risk function risk(y,f,w) with respect to f. By default, the risk function is the weighted sum of the loss function loss(y,f) but can be chosen arbitrarily. The ngradient(y,f) function is the negative gradient of loss(y,f) with respect to f.

Pre-fabricated functions for the most commonly used loss functions are available as well. Buehlmann and Hothorn (2007) give a detailed overview of the available loss functions. An updated overview can be found in Hofner et al (2014).

The offset function returns the population minimizers evaluated at the response, i.e., $1/2\log(p/(1-p))$ for Binomial() or AdaExp() and $(\sum w_i)^{-1}\sum w_i y_i$ for Gaussian() and the median for Huber() and Laplace(). The offset is used as starting value for the boosting algorithm.

Note that all families are functions and thus need to be specified either with empty brackets (e.g., family = Gaussian() for Gaussian regression) or with additional arguments if these are supported by the respective family (e.g., family = QuantReg(tau = 0.2) for quantile regression for the 20% quantile).

A short summary of the available families is given in the following paragraphs:

AdaExp(), Binomial() and AUC() implement families for binary classification. AdaExp() uses the exponential loss, which essentially leads to the AdaBoost algorithm of Freund and Schapire (1996). Binomial() implements the negative binomial log-likelihood of a logistic regression model as loss function. Thus, using Binomial family closely corresponds to fitting a logistic model. Alternative link functions can be specified.

However, the coefficients resulting from boosting with family Binomial(link = "logit") are $1/2$ of the coefficients of a logit model obtained via [glm](#). Buehlmann and Hothorn (2007) argue that the family Binomial is the preferred choice for binary classification. For binary classification problems the response y has to be a factor. Internally y is re-coded to -1 and $+1$ (Buehlmann and Hothorn 2007).

Binomial(type = "glm") is an alternative to Binomial() leading to coefficients of the same size as coefficients from a classical logit model via [glm](#). Additionally, it works not only with a two-level factor but also with a two-column matrix containing the number of successes and number of failures (again, similar to [glm](#)).

AUC() uses $1 - AUC(y, f)$ as the loss function. The area under the ROC curve (AUC) is defined as $AUC = (n_{-1}n_1)^{-1}\sum_{i:y_i=1}\sum_{j:y_j=-1}I(f_i > f_j)$. Since this is not differentiable in f, we

approximate the jump function $I((f_i - f_j) > 0)$ by the distribution function of the triangular distribution on $[-1, 1]$ with mean 0, similar to the logistic distribution approximation used in Ma and Huang (2005).

Gaussian() is the default family in [mboost]. It implements L_2Boosting for continuous response. Note that families GaussReg() and GaussClass() (for regression and classification) are deprecated now. Huber() implements a robust version for boosting with continuous response, where the Huber-loss is used. Laplace() implements another strategy for continuous outcomes and uses the L_1-loss instead of the L_2-loss as used by Gaussian().

Poisson() implements a family for fitting count data with boosting methods. The implemented loss function is the negative Poisson log-likelihood. Note that the natural link function $\log(\mu) = \eta$ is assumed. The default step-site nu = 0.1 is probably too large for this family (leading to infinite residuals) and smaller values are more appropriate.

GammaReg() implements a family for fitting nonnegative response variables. The implemented loss function is the negative Gamma log-likelihood with logarithmic link function (instead of the natural link).

CoxPH() implements the negative partial log-likelihood for Cox models. Hence, survival models can be boosted using this family.

QuantReg() implements boosting for quantile regression, which is introduced in Fenske et al. (2009). ExpectReg works in analogy, only for expectiles, which were introduced to regression by Newey and Powell (1987).

Families with an additional scale parameter can be used for fitting models as well: PropOdds() leads to proportional odds models for ordinal outcome variables (Schmid et al., 2011). When using this family, an ordered set of threshold parameters is re-estimated in each boosting iteration. An example is given below which also shows how to obtain the thresholds. NBinomial() leads to regression models with a negative binomial conditional distribution of the response. Weibull(), Loglog(), and Lognormal() implement the negative log-likelihood functions of accelerated failure time models with Weibull, log-logistic, and lognormal distributed outcomes, respectively. Hence, parametric survival models can be boosted using these families. For details see Schmid and Hothorn (2008) and Schmid et al. (2010).

Gehan() implements rank-based estimation of survival data in an accelerated failure time model. The loss function is defined as the sum of the pairwise absolute differences of residuals. The response needs to be defined as Surv(y, delta), where y is the observed survial time (subject to censoring) and delta is the non-censoring indicator (see [Surv] for details). For details on Gehan() see Johnson and Long (2011).

Cindex() optimizes the concordance-index for survival data (often denoted as Harrell's C or C-index). The concordance index evaluates the rank-based concordance probability between the model and the outcome. The C-index measures whether large values of the model are associated with short survival times and vice versa. The interpretation is similar to the AUC: A C-index of 1 represents a perfect discrimination while a C-index of 0.5 will be achieved by a completely non-informative marker. The Cindex() family is based on an estimator by Uno et al. (2011), which incorporates inverse probability of censoring weighting ipcw. To make the estimator differentiable, sigmoid functions are applied; the corresponding smoothness can be controlled via sigma. For details on Cindex() see Mayr and Schmid (2014).

Hurdle models for zero-inflated count data can be fitted by using a combination of the Binomial() and Hurdle() families. While the Binomial() family allows for fitting the zero-generating process of the Hurdle model, Hurdle() fits a negative binomial regression model to the non-zero counts.

Note that the specification of the Hurdle model allows for using `Binomial()` and `Hurdle()` independently of each other.

Linear or additive multinomial logit models can be fitted using `Multinomial()`; although is family requires some extra effort for model specification (see example). More specifically, the predictor must be in the form of a linear array model (see `%O%`). Note that this family does not work with tree-based base-learners at the moment. The class corresponding to the last level of the factor coding of the response is used as reference class.

`RCG()` implements the ratio of correlated gammas (RCG) model proposed by Weinhold et al. (2016).

Value

An object of class `boost_family`.

Warning

The coefficients resulting from boosting with family `Binomial(link = "logit")` are $1/2$ of the coefficients of a logit model obtained via `glm` (see above).

For `AUC()`, variables should be centered and scaled and observations with weight > 0 must not contain missing values. The estimated coefficients for `AUC()` have no probabilistic interpretation.

Examples

```
### Define a new family
MyGaussian <- function(){
      Family(ngradient = function(y, f, w = 1) y - f,
      loss = function(y, f) (y - f)^2,
      name = "My Gauss Variant")
}
# Now use the new family
data(bodyfat, package = "TH.data")
mod <- mboost(DEXfat ~ ., data = bodyfat, family = MyGaussian())
# N.B. that the family needs to be called with empty brackets

### Proportional odds model
data(iris)
iris$Species <- factor(iris$Species, ordered = TRUE)
if (require("MASS")) {
    (mod.polr <- polr(Species  ~ Sepal.Length, data = iris))
}
mod.PropOdds <- glmboost(Species  ~ Sepal.Length, data = iris,
                        family = PropOdds(nuirange = c(-0.5, 3)))
mstop(mod.PropOdds) <- 1000
## thresholds are treated as nuisance parameters, to extract these use
nuisance(mod.PropOdds)
## effect estimate
coef(mod.PropOdds)["Sepal.Length"]
```

```
## make thresholds comparable to a model without intercept
nuisance(mod.PropOdds) - coef(mod.PropOdds)["(Intercept)"] -
    attr(coef(mod.PropOdds), "offset")

### Multinomial logit model via a linear array model
## One needs to convert the data to a list
myiris <- as.list(iris)
## ... and define a dummy vector with one factor level less
## than the outcome, which is used as reference category.
myiris$class <- factor(levels(iris$Species)[-nlevels(iris$Species)])
## Now fit the linear array model
mlm <- mboost(Species ~ bols(Sepal.Length, df = 2) %O%
                         bols(class, df = 2, contrasts.arg = "contr.dummy"),
              data = myiris,
              family = Multinomial())
coef(mlm) ## one should use more boosting iterations.
head(round(pred <- predict(mlm, type = "response"), 2))

## Prediction with new data:
newdata <- as.list(iris[1,])
## One always needs to keep the dummy vector class as above!
newdata$class <- factor(levels(iris$Species)[-nlevels(iris$Species)])
pred2 <- predict(mlm, type = "response", newdata = newdata)
## check results
pred[1, ]
pred2

## Not run: ###########################################################
## Do not run and check these examples automatically as
## they take some time

## Compare results with nnet::multinom
if (require("nnet")) {
    mlmn <- multinom(Species ~ Sepal.Length, data = iris)
    max(abs(fitted(mlm[1000], type = "response") -
            fitted(mlmn, type = "prob")))
}

## End(Not run and test)

## End(Not run)

### Example for RCG model
## generate covariate values
set.seed(12345)
x1 <- rnorm(500)
x2 <- rnorm(500)
## generate linear predictors
zetaM <- 0.1 + 0.3 * x1 - 0.5 * x2
zetaU <- 0.1 - 0.1 * x1 + 0.2 * x2
## generate beta values
M <- rgamma(500, shape = 2, rate = exp(zetaM))
```

```
U <- rgamma(500, shape = 2, rate = exp(zetaU))
y <- M / (M + U)

## fit RCG model
data <- data.frame(y, x1, x2)
RCGmodel <- glmboost(y ~ x1 + x2, data = data, family = RCG(),
                     control = boost_control(mstop = 1000,
                     trace = TRUE, nu = 0.01))
## true coefficients: gamma = (0.0, 0.4, -0.7),
##                     alpha (= shape) = 2,
##                     rho = 0
## compare to coefficient estimates
coef(RCGmodel)
nuisance(RCGmodel)

## compute downstream tests
## (only suitable without early stopping, i.e., if likelihood based model converged)
downstream.test(RCGmodel)

## compute conditional expectations
predictions <- predict(RCGmodel, type = "response")
plot(predictions, y)
abline(0,1)
```

FP   *Fractional Polynomials*

Description

Fractional polynomials transformation for continuous covariates.

Usage

```
FP(x, p = c(-2, -1, -0.5, 0.5, 1, 2, 3), scaling = TRUE)
```

Arguments

x   a numeric vector.

p   all powers of x to be included.

scaling   a logical indicating if the measurements are scaled prior to model fitting.

Details

A fractional polynomial refers to a model $\sum_{j=1}^{k}(\beta_j x^{p_j} + \gamma_j x^{p_j} \log(x)) + \beta_{k+1} \log(x) + \gamma_{k+1} \log(x)^2$, where the degree of the fractional polynomial is the number of non-zero regression coefficients β and γ.

Value

A matrix including all powers p of x, all powers p of log(x), and log(x).

glmboost   *Gradient Boosting with Component-wise Linear Models*

Description

Gradient boosting for optimizing arbitrary loss functions where component-wise linear models are utilized as base-learners.

Usage

```
## S3 method for class 'formula'
glmboost(formula, data = list(), weights = NULL,
         offset = NULL, family = Gaussian(),
         na.action = na.pass, contrasts.arg = NULL,
         center = TRUE, control = boost_control(), oobweights = NULL, ...)
## S3 method for class 'matrix'
glmboost(x, y, center = TRUE, weights = NULL,
         offset = NULL, family = Gaussian(),
        na.action = na.pass, control = boost_control(), oobweights = NULL, ...)
## Default S3 method:
glmboost(x, ...)
```

Arguments

formula	a symbolic description of the model to be fit.
data	a data frame containing the variables in the model.
weights	an optional vector of weights to be used in the fitting process.
offset	a numeric vector to be used as offset (optional).
family	a [Family](#) object.
na.action	a function which indicates what should happen when the data contain NAs.
contrasts.arg	a list, whose entries are contrasts suitable for input to the `contrasts` replacement function and whose names are the names of columns of `data` containing factors. See [model.matrix.default](#).
center	logical indicating of the predictor variables are centered before fitting.
control	a list of parameters controlling the algorithm. For more details see [boost_control](#).
oobweights	an additional vector of out-of-bag weights, which is used for the out-of-bag risk (i.e., if `boost_control(risk = "oobag")`). This argument is also used internally by `cvrisk`.
x	design matrix. Sparse matrices of class `Matrix` can be used as well.
y	vector of responses.
...	additional arguments passed to [mboost_fit](#); currently none.

Details

A (generalized) linear model is fitted using a boosting algorithm based on component-wise univariate linear models. The fit, i.e., the regression coefficients, can be interpreted in the usual way. The methodology is described in Buehlmann and Yu (2003), Buehlmann (2006), and Buehlmann and Hothorn (2007). Examples and further details are given in Hofner et al (2014).

Value

An object of class glmboost with [print](#), [coef](#), [AIC](#) and [predict](#) methods being available. For inputs with longer variable names, you might want to change par("mai") before calling the plot method of glmboost objects visualizing the coefficients path.

beta <- numeric(p)
beta[sample(1:p, ptrue)] <- 10
y <- drop(X %*% beta + rnorm(n, sd = 0.1))
mod <- glmboost(y = y, x = X, center = TRUE) ### mstop needs tuning
coef(mod, which = which(beta > 0))
```

IPCweights   *Inverse Probability of Censoring Weights*

Description

Compute weights for censored regression via the inverted probability of censoring principle.

Usage

```
IPCweights(x, maxweight = 5)
```

Arguments

x   an object of class Surv.

maxweight   the maximal value of the returned weights.

Details

Inverse probability of censoring weights are one possibility to fit models formulated in the *full data world* in the presence of censoring, i.e., the *observed data world*, see van der Laan and Robins (2003) for the underlying theory and Hothorn et al. (2006) for an application to survival analysis.

Value

A vector of numeric weights.

mboost   *Gradient Boosting for Additive Models*

Description

Gradient boosting for optimizing arbitrary loss functions, where component-wise arbitrary base-learners, e.g., smoothing procedures, are utilized as additive base-learners.

Usage

```
mboost(formula, data = list(), na.action = na.omit, weights = NULL,
       offset = NULL, family = Gaussian(), control = boost_control(),
       oobweights = NULL, baselearner = c("bbs", "bols", "btree", "bss", "bns"),
       ...)

gamboost(formula, data = list(), na.action = na.omit, weights = NULL,
         offset = NULL, family = Gaussian(), control = boost_control(),
         oobweights = NULL, baselearner = c("bbs", "bols", "btree", "bss", "bns"),
         dfbase = 4, ...)
```

Arguments

formula	a symbolic description of the model to be fit.
data	a data frame containing the variables in the model.
na.action	a function which indicates what should happen when the data contain NAs.
weights	(optional) a numeric vector of weights to be used in the fitting process.
offset	a numeric vector to be used as offset (optional).
family	a [Family](#) object.
control	a list of parameters controlling the algorithm. For more details see [boost_control](#).
oobweights	an additional vector of out-of-bag weights, which is used for the out-of-bag risk (i.e., if boost_control(risk = "oobag")). This argument is also used internally by cvrisk.
baselearner	a character specifying the component-wise base learner to be used: [bbs](#) means P-splines with a B-spline basis (see Schmid and Hothorn 2008), [bols](#) linear models and [btree](#) boosts stumps. bss and bns are deprecated. Component-wise smoothing splines have been considered in Buehlmann and Yu (2003) and Schmid and Hothorn (2008) investigate P-splines with a B-spline basis. Kneib, Hothorn and Tutz (2009) also utilize P-splines with a B-spline basis, supplement them with their bivariate tensor product version to estimate interaction surfaces and spatial effects and also consider random effects base learners.
dfbase	a single integer giving the degrees of freedom for P-spline base-learners ([bbs](#)) globally.
...	additional arguments passed to [mboost_fit](#); currently none.

Details

A (generalized) additive model is fitted using a boosting algorithm based on component-wise base-learners.

The base-learners can either be specified via the formula object or via the baselearner argument. The latter argument is the default base-learner which is used for all variables in the formula, whithout explicit base-learner specification (i.e., if the base-learners are explicitly specified in formula, the baselearner argument will be ignored for this variable).

Of note, "bss" and "bns" are deprecated and only in the list for backward compatibility.

Note that more base-learners (i.e., in addition to the ones provided via baselearner) can be specified in formula. See baselearners for details.

The only difference when calling mboost and gamboost is that the latter function allows one to specify default degrees of freedom for smooth effects specified via baselearner = "bbs". In all other cases, degrees of freedom need to be set manually via a specific definition of the corresponding base-learner.

Value

An object of class mboost with print, AIC, plot and predict methods being available.

mboost_fit   *Model-based Gradient Boosting*

Description

Work-horse for gradient boosting for optimizing arbitrary loss functions, where component-wise models are utilized as base-learners. Usually, this function is not called directly by the user.

Usage

```
mboost_fit(blg, response, weights = rep(1, NROW(response)), offset = NULL,
           family = Gaussian(), control = boost_control(), oobweights =
           as.numeric(weights == 0))
```

Arguments

blg   a list of objects of elements of class blg, as returned by all base-learners.

response   the response variable.

weights   (optional) a numeric vector of weights to be used in the fitting process.

offset   a numeric vector to be used as offset (optional).

family   a [Family](#) object.

control   a list of parameters controlling the algorithm. For more details see [boost_control](#).

oobweights an additional vector of out-of-bag weights, which is used for the out-of-bag risk (i.e., if boost_control(risk = "oobag")). This argument is also used internally by cvrisk.

Details

The function implements component-wise functional gradient boosting in a generic way. This function is the main work horse and used as back-end by all boosting algorithms in a unified way. Usually, this function is not called directly. Note that the more convenient modelling interfaces gamboost, glmboost and blackboost all call mboost_fit.

Basically, the algorithm is initialized with a function for computing the negative gradient of the loss function (via its `family` argument) and one or more base-learners (given as `blg`). Usually `blg` and `response` are computed in the functions gamboost, glmboost, blackboost or mboost. See there for details on the specification of base-learners.

The algorithm minimized the in-sample empirical risk defined as the weighted sum (by `weights`) of the loss function (corresponding to the negative gradient) evaluated at the data.

The structure of the model is determined by the structure of the base-learners. If more than one base-learner is given, the model is additive in these components.

Base-learners can be specified via a formula interface (function `mboost`) or as a list of objects of class bl, see, e.g., bols.

oobweights is a vector used internally by cvrisk. When carrying out cross-validation to determine the optimal stopping iteration of a boosting model, the default value of oobweights (out-of-bag weights) assures that the cross-validated risk is computed using the same observation weights as those used for fitting the boosting model. It is strongly recommended to leave this argument unspecified.

Value

An object of class mboost with print, AIC, plot and predict methods being available.

```

Arguments

object	objects of class `glmboost`, `gamboost`, `blackboost` or `gbAIC`.
x	objects of class `glmboost` or `gamboost`.
model	objects of class mboost
newdata	optionally, a data frame in which to look for variables with which to predict. In case the model was fitted using the `matrix` interface to [glmboost](), `newdata` must be a `matrix` as well (an error is given otherwise).
which	a subset of base-learners to take into account for computing predictions or coefficients. If `which` is given (as an integer vector or characters corresponding to base-learners) a list or matrix is returned.
usedonly	logical. Indicating whether all variable names should be returned or only those selected in the boosting algorithm.
type	the type of prediction required. The default is on the scale of the predictors; the alternative `"response"` is on the scale of the response variable. Thus for a binomial model the default predictions are of log-odds (probabilities on logit scale) and type = `"response"` gives the predicted probabilities. The `"class"` option returns predicted classes.
aggregate	a character specifying how to aggregate predictions or coefficients of single base-learners. The default returns the prediction or coefficient for the final number of boosting iterations. `"cumsum"` returns a list with matrices (one per base-learner) with the cumulative coefficients for all iterations simultaneously (in columns). `"none"` returns a list of matrices where the jth columns of the respective matrix contains the predictions of the base-learner of the jth boosting iteration (and zero if the base-learner is not selected in this iteration).

off2int	logical. Indicating whether the offset should be added to the intercept (if there is any) or if the offset is returned as attribute of the coefficient (default).
i	integer. Index specifying the model to extract. If i = 0, the offset model is returned. If i is smaller than the initial mstop, a subset is used. If i is larger than the initial mstop, additional boosting steps are performed until step i is reached. See details for more information.
value	integer. See i.
return	a logical indicating whether the changed object is returned.
method	a character specifying if the corrected AIC criterion or a classical (-2 logLik + k * df) should be computed.
df	a character specifying how degrees of freedom should be computed: trace defines degrees of freedom by the trace of the boosting hat matrix and actset uses the number of non-zero coefficients for each boosting iteration.
k	numeric, the *penalty* per parameter to be used; the default k = 2 is the classical AIC. Only used when method = "classical".
what	a character specifying the quantities to extract. Depending on object this can be a subset of "design" (default; design matrix), "penalty" (penalty matrix), "lambda" (smoothing parameter), "df" (degrees of freedom), "coefficients", "residuals", "variable.names", "bnames" (names of the base-learners), "offset", "nuisance", "weights", "index" (index of ties used to expand the design matrix) and "control". In future versions additional extractors might be specified.
asmatrix	a logical indicating whether the the returned matrix should be coerced to a matrix (default) or if the returned object stays as it is (i.e., potentially a *sparse* matrix). This option is only applicable if extract returns matrices, i.e., what = "design" or what = "penalty".
expand	a logical indicating whether the design matrix should be expanded (default: FALSE). This is useful if ties where taken into account either manually (via argument index in a base-learner) or automatically for data sets with many observations. expand = TRUE is equivalent to extract(B)[extract(B,what = "index"),] for a base-learner B.
...	additional arguments passed to callies.

Details

These functions can be used to extract details from fitted models. print shows a dense representation of the model fit and summary gives a more detailed representation.

The function coef extracts the regression coefficients of a linear model fitted using the [glmboost](#) function or an additive model fitted using the [gamboost](#). Per default, only coefficients of selected base-learners are returned. However, any desired coefficient can be extracted using the which argument (see examples for details). Per default, the coefficient of the final iteration is returned (aggregate = "sum") but it is also possible to return the coefficients from all iterations simultaniously (aggregate = "cumsum"). If aggregate = "none" is specified, the coefficients of the *selected* base-learners are returned (see examples below). For models fitted via [glmboost](#) with option center = TRUE the intercept is rarely selected. However, it is implicitly estimated through the centering of the design matrix. In this case the intercept is always returned except which is specified such that the intercept is not selected. See examples below.

The `predict` function can be used to predict the status of the response variable for new observations whereas `fitted` extracts the regression fit for the observations in the learning sample. For `predict` `newdata` can be specified, otherwise the fitted values are returned. If `which` is specified, marginal effects of the corresponding base-learner(s) are returned. The argument `type` can be used to make predictions on the scale of the `link` (i.e., the linear predictor $X\beta$), the `response` (i.e. $h(X\beta)$, where h is the response function) or the `class` (in case of classification). Furthermore, the predictions can be aggregated analogously to `coef` by setting `aggregate` to either `sum` (default; predictions of the final iteration are given), `cumsum` (predictions of all iterations are returned simultaniously) or `none` (change of prediction in each iteration). If applicable the `offset` is added to the predictions. If marginal predictions are requested the `offset` is attached to the object via `attr(..., "offset")` as adding the offset to one of the marginal predictions doesn't make much sense.

The `[.mboost` function can be used to enhance or restrict a given boosting model to the specified boosting iteration `i`. Note that in both cases the original x will be changed to reduce the memory footprint. If the boosting model is enhanced by specifying an index that is larger than the initial `mstop`, only the missing `i -mstop` steps are fitted. If the model is restricted, the spare steps are not dropped, i.e., if we increase `i` again, these boosting steps are immediately available. Alternatively, the same operation can be done by `mstop(x) <-i`.

The `residuals` function can be used to extract the residuals (i.e., the negative gradient of the current iteration). `resid` is is an alias for `residuals`.

Variable names (including those of interaction effects specified via by in a base-learner) can be extracted using the generic function `variable.names`, which has special methods for boosting objects.

The generic `extract` function can be used to extract various characteristics of a fitted model or a base-learner. Note that the sometimes a penalty function is returned (e.g. by `extract(bols(x),what = "penalty")`) even if the estimation is unpenalized. However, in this case the penalty paramter `lambda` is set to zero. If a matrix is returned by `extract` one can to set `asmatrix = TRUE` if the returned matrix should be coerced to class `matrix`. If `asmatrix = FALSE` one might get a sparse matrix as implemented in package `Matrix`. If one requests the design matrix (`what = "design"`) `expand = TRUE` expands the resulting matrix by taking the duplicates handeled via `index` into account.

The ids of base-learners selected during the fitting process can be extracted using `selected()`. The `nuisance()` method extracts nuisance parameters from the fit that are handled internally by the corresponding family object, see "boost_family". The `risk()` function can be used to extract the computed risk (either the `"inbag"` risk or the `"oobag"` risk, depending on the control argument; see boost_control).

For (generalized) linear and additive models, the `AIC` function can be used to compute both the classical AIC (only available for `familiy = Binomial()` and `familiy = Poisson()`) and corrected AIC (Hurvich et al., 1998, only available when `family = Gaussian()` was used). Details on the used approximations for the hat matrix can be found in Buehlmann and Hothorn (2007). The AIC is useful for the determination of the optimal number of boosting iterations to be applied (which can be extracted via `mstop`). The degrees of freedom are either computed via the trace of the boosting hat matrix (which is rather slow even for moderate sample sizes) or the number of variables (non-zero coefficients) that entered the model so far (faster but only meaningful for linear models fitted via gamboost (see Hastie, 2007)). For a discussion of the use of AIC based stopping see also Mayr, Hofner and Schmid (2012).

In addition, the general Minimum Description Length criterion (Buehlmann and Yu, 2006) can be computed using function `AIC`.

Note that `logLik` and `AIC` only make sense when the corresponding [Family](#) implements the appropriate loss function.

`downstream.test` computes tests for linear models fitted via [glmboost](#) with a likelihood based loss function and only suitable without early stopping, i.e., if likelihood based model converged. In order to work, the Fisher matrix must be implemented in the [Family](#); currently this is only the case for family [RCG](#).

Warning

The coefficients resulting from boosting with family `Binomial(link = "logit")` are $1/2$ of the coefficients of a logit model obtained via [glm](#) (see [Binomial](#)).

Note

The `[.mboost` function changes the original object, i.e. `gbmodel[10]` changes `gbmodel` directly!

Examples

```
### a simple two-dimensional example: cars data
cars.gb <- glmboost(dist ~ speed, data = cars,
```

```
                              control = boost_control(mstop = 2000),
                              center = FALSE)
        cars.gb

        ### initial number of boosting iterations
        mstop(cars.gb)

        ### AIC criterion
        aic <- AIC(cars.gb, method = "corrected")
        aic

        ### extract coefficients for glmboost
        coef(cars.gb)
        coef(cars.gb, off2int = TRUE)        # offset added to intercept
        coef(lm(dist ~ speed, data = cars))  # directly comparable

        cars.gb_centered <- glmboost(dist ~ speed, data = cars,
                                     center = TRUE)
        selected(cars.gb_centered)           # intercept never selected
        coef(cars.gb_centered)               # intercept implicitly estimated
                                             # and thus returned
        ## intercept is internally corrected for mean-centering
        - mean(cars$speed) * coef(cars.gb_centered, which="speed") # = intercept
        # not asked for intercept thus not returned
        coef(cars.gb_centered, which="speed")
        # explicitly asked for intercept
        coef(cars.gb_centered, which=c("Intercept", "speed"))

        ### enhance or restrict model
        cars.gb <- gamboost(dist ~ speed, data = cars,
                            control = boost_control(mstop = 100, trace = TRUE))
        cars.gb[10]
        cars.gb[100, return = FALSE] # no refitting required
        cars.gb[150, return = FALSE] # only iterations 101 to 150
                                     # are newly fitted

        ### coefficients for optimal number of boosting iterations
        coef(cars.gb[mstop(aic)])
        plot(cars$dist, predict(cars.gb[mstop(aic)]),
             ylim = range(cars$dist))
        abline(a = 0, b = 1)

        ### example for extraction of coefficients
        set.seed(1907)
        n <- 100

plot   *Plot effect estimates of boosting models*

Description

Plot coefficient plots for glmboost models and partial effect plots for all other mboost models.

Usage

```
## S3 method for class 'glmboost'
plot(x, main = deparse(x$call), col = NULL,
     off2int = FALSE, ...)

## S3 method for class 'mboost'
plot(x, which = NULL, newdata = NULL,
     type = "b", rug = TRUE, rugcol = "black",
     ylim = NULL, xlab = NULL, ylab = expression(f[partial]),
     add = FALSE, ...)

## S3 method for class 'mboost'
lines(x, which = NULL, type = "l", rug = FALSE, ...)
```

Arguments

x	object of class glmboost or an object inheriting from mboost for plotting.
main	a title for the plot.
col	(a vector of) colors for plotting the lines representing the coefficient paths.
off2int	logical indicating whether the offset should be added to the intercept (if there is any) or if the offset is neglected for plotting (default).
which	a subset of base-learners used for plotting. If which is given (as an integer vector or characters corresponding to base-learners) only the corresponding partial effect plots are depicted. Per default all selected base-learners are plotted.
newdata	optionally, a data frame in which to look for variables with which to make predictions that are then plotted. This is especially useful if the data that was used to fit the model shows some larger gaps as effect plots are linearly interpolated between observations. For an example using newdata see below.
type	character string giving the type of plot desired. Per default, points and lines are plotted ("b"). Other useful options are points ("p") or lines ("l"). See plot.default for details.
rug	logical. Should a rug be added to the x-axis?
rugcol	color for the rug.
ylim	the y limits of the plot.

xlab	a label for the x axis.
ylab	a label for the y axis.
add	logical. Should the plot be added to the previous plot?
...	Additional arguments to the `plot` functions. E.g. one can specify the x limits `xlim` or the color of the plot using `col`.

Details

The coefficient paths for `glmboost` models show how the coefficient estimates evolve with increasing `mstop`. Each line represents one parameter estimate. Parameter estimates are only depicted when they they are selected at any time in the boosting model. Parameters that are not selected are droped from the figure (see example).

Models specified with `gamboost` or `mboost` are plotted as partial effects. Only the effect of the current bossting iteration is depicted instead of the coefficient paths as for linear models. The function `lines` is just a wrapper to `plot(... ,add = TRUE)` where per default the effect is plotted as line and the `rug` is set to `FALSE`.

Spatial effects can be also plotted using the function `plot` for mboost models (using `lattice` graphics). More complex effects reuquire manual plotting: One needs to predict the effects on a disired grid and plot the effect estimates.

Value

A plot of the fitted model.

[mboost_methods](#) for further methods.

Examples

```
### a simple example: cars data with one random variable
set.seed(1234)
cars$z <- rnorm(50)

#########################################
## Plot linear models
#########################################

## fit a linear model
cars.lm <- glmboost(dist ~ speed + z, data = cars)
```

```
## plot coefficient paths of glmboost
par(mfrow = c(3, 1), mar = c(4, 4, 4, 8))
plot(cars.lm,
     main = "Coefficient paths (offset not included)")
plot(cars.lm, off2int = TRUE,
     main = "Coefficient paths (offset included in intercept)")

## plot coefficient paths only for the first 15 steps,
## i.e., bevore z is selected
mstop(cars.lm) <- 15
plot(cars.lm, off2int = TRUE, main = "z is not yet selected")

#########################################
## Plot additive models; basics
#########################################

## fit an additive model
cars.gam <- gamboost(dist ~ speed + z, data = cars)

## plot effects
par(mfrow = c(1, 2), mar = c(4, 4, 0.1, 0.1))
plot(cars.gam)

## use same y-lims
plot(cars.gam, ylim = c(-50, 50))

## plot only the effect of speed
plot(cars.gam, which = "speed")
## as partial matching is used we could also use
plot(cars.gam, which = "sp")

#########################################
## More complex plots
#########################################

## Let us use more boosting iterations and compare the effects.

## We change the plot type and plot both effects in one figure:
par(mfrow = c(1, 1), mar = c(4, 4, 4, 0.1))
mstop(cars.gam) <- 100
plot(cars.gam, which = 1, col = "red", type = "l", rug = FALSE,
     main = "Compare effect for various models")

## Now the same model with 1000 iterations
mstop(cars.gam) <- 1000
lines(cars.gam, which = 1, col = "grey", lty = "dotted")

## There are some gaps in the data. Use newdata to get a smoother curve:
newdata <- data.frame(speed = seq(min(cars$speed), max(cars$speed),
                                   length = 200))
lines(cars.gam, which = 1, col = "grey", lty = "dashed",
```

```
        newdata = newdata)

## The model with 1000 steps seems to overfit the data.
## Usually one should use e.g. cross-validation to tune the model.

## Finally we refit the model using linear effects as comparison
cars.glm <- gamboost(dist ~ speed + z, baselearner = bols, data = cars)
lines(cars.glm, which = 1, col = "black")
## We see that all effects are more or less linear.

## Add a legend
legend("topleft", title = "Model",
       legend = c("... with mstop = 100", "... with mstop = 1000",
         "... with linear effects"),
       lty = c("solid", "dashed", "solid"),
       col = c("red", "grey", "black"))
```

---

stabsel   *Stability Selection*

Description

Selection of influential variables or model components with error control.

Usage

```
## a method to compute stability selection paths for fitted mboost models
## S3 method for class 'mboost'
stabsel(x, cutoff, q, PFER, grid = 0:mstop(x),
        folds = subsample(model.weights(x), B = B),
        B = ifelse(sampling.type == "MB", 100, 50),
        assumption = c("unimodal", "r-concave", "none"),
        sampling.type = c("SS", "MB"),
        papply = mclapply, verbose = TRUE, FWER, eval = TRUE, ...)

## just a wrapper to stabsel(p, ..., eval = FALSE)
## S3 method for class 'mboost'
stabsel_parameters(p, ...)
```

Arguments

x, p	an fitted model of class "mboost".
cutoff	cutoff between 0.5 and 1. Preferably a value between 0.6 and 0.9 should be used.
q	number of (unique) selected variables (or groups of variables depending on the model) that are selected on each subsample.

PFER	upper bound for the per-family error rate. This specifies the amount of falsely selected base-learners, which is tolerated. See details.
grid	a numeric vector of the form `0:m`. See also [cvrisk]().
folds	a weight matrix with number of rows equal to the number of observations, see [cvrisk]() and [subsample](). Usually one should not change the default here as subsampling with a fraction of $1/2$ is needed for the error bounds to hold. One usage scenario where specifying the folds by hand might be the case when one has dependent data (e.g. clusters) and thus wants to draw clusters (i.e., multiple rows together) not individuals.
assumption	Defines the type of assumptions on the distributions of the selection probabilities and simultaneous selection probabilities. Only applicable for `sampling.type = "SS"`. For `sampling.type = "MB"` we always use code"none".
sampling.type	use sampling scheme of of Shah & Samworth (2013), i.e., with complementarty pairs (`sampling.type = "SS"`), or the original sampling scheme of Meinshausen & Buehlmann (2010).
B	number of subsampling replicates. Per default, we use 50 complementary pairs for the error bounds of Shah & Samworth (2013) and 100 for the error bound derived in Meinshausen & Buehlmann (2010). As we use B complementray pairs in the former case this leads to $2B$ subsamples.
papply	(parallel) apply function, defaults to [mclapply](). Alternatively, `parLapply` can be used. In the latter case, usually more setup is needed (see example of [cvrisk]() for some details).
verbose	logical (default: `TRUE`) that determines wether `warnings` should be issued.
FWER	deprecated. Only for compatibility with older versions, use PFER instead.
eval	logical. Determines whether stability selection is evaluated (`eval = TRUE`; default) or if only the parameter combination is returned.
...	additional arguments to parallel apply methods such as [mclapply]() and to [cvrisk]().

Details

For details see [stabsel]() in package **stabs** and Hofner et al. (2015).

Value

An object of class `stabsel` with a special `print` method. The object has the following elements:

phat	selection probabilities.
selected	elements with maximal selection probability greater `cutoff`.
max	maximum of selection probabilities.
cutoff	cutoff used.
q	average number of selected variables used.
PFER	per-family error rate.
sampling.type	the sampling type used for stability selection.
assumption	the assumptions made on the selection probabilities.
call	the call.

survFit   *Survival Curves for a Cox Proportional Hazards Model*

Description

Computes the predicted survivor function for a Cox proportional hazards model.

Usage

```
## S3 method for class 'mboost'
survFit(object, newdata = NULL, ...)
## S3 method for class 'survFit'
plot(x, xlab = "Time", ylab = "Probability", ...)
```

Arguments

object	an object of class mboost which is assumed to have a [CoxPH](#) family component.
newdata	an optional data frame in which to look for variables with which to predict the survivor function.
x	an object of class survFit for plotting.
xlab	the label of the x axis.
ylab	the label of the y axis.
...	additional arguments passed to callies.

Details

If newdata = NULL, the survivor function of the Cox proportional hazards model is computed for the mean of the covariates used in the [blackboost](#), [gamboost](#), or [glmboost](#) call. The Breslow estimator is used for computing the baseline survivor function. If newdata is a data frame, the [predict](#) method of object, along with the Breslow estimator, is used for computing the predicted survivor function for each row in newdata.

Value

An object of class survFit containing the following components:

surv	the estimated survival probabilities at the time points given in time.
time	the time points at which the survivor functions are evaluated.
n.event	the number of events observed at each time point given in time.

See Also

[gamboost](#), [glmboost](#) and [blackboost](#) for model fitting.

Examples

```
library("survival")
data("cancer", package = "survival")

fm <- Surv(futime,fustat) ~ age + resid.ds + rx + ecog.ps
fit <- glmboost(fm, data = ovarian, family = CoxPH(),
    control=boost_control(mstop = 500))

S1 <- survFit(fit)
S1
newdata <- ovarian[c(1,3,12),]
S2 <- survFit(fit, newdata = newdata)
S2

plot(S1)
```

---

varimp   *Variable Importance*

Description

In-bag risk reduction per base-learner as variable importance for boosting.

Usage

```
## S3 method for class 'mboost'
varimp(object, ...)

## S3 method for class 'varimp'
plot(x, percent = TRUE, type = c("variable", "blearner"),
  blorder = c("importance", "alphabetical", "rev_alphabetical", "formula"),
  nbars = 10L, maxchar = 20L, xlab = NULL, ylab = NULL, xlim, auto.key, ...)
## S3 method for class 'varimp'
as.data.frame(x, row.names = NULL, optional = FALSE, ...)
```

Arguments

object	an object of class mboost.
x	an object of class varimp.
percent	logical, indicating whether variable importance should be specified in percent.
type	a character string specifying whether to draw bars for variables ("variable", default) or base-learners ("blearner") in the model (no effect for a glmboost object).

blorder	a character string specifying the order of the base-learners in the plot. The default `"importance"` corresponds to the order of the base-learner importance, `"alphabetical"` and `"rev_alphabetical"` to alphabetical order, respectively its reverse, and `"formula"` to their order in the model formula.
nbars	integer, maximum number of bars to be plotted. If `nbars` is exceeded, least important variables / base-learners are summarized as "other".
maxchar	integer, maximum number of characters in bar labels.
xlab	text for the x-axis label. If not set (default is NULL) x-axis label is generated automatically depending on argument `percent`.
ylab	text for the y-axis label. If not set (default is NULL) y-axis label is generated automatically depending on argument `type`.
xlim	the x limits of the plot. Defaults are from 0 to total reduction, or from 0 to 1 for `percent = TRUE`. (In case of negative risk reductions, default limits are from total negative to total positve reduction, or the latter normalized by the total absolute reduction for `percent = TRUE`.)
auto.key	logical, or a list passed to `lattice::barchart`. By default `auto.key=TRUE` provides automatically generated legends showing the underlying base-learners in the stacked barchart (`type = "variable"`). If there is an unique base-learner for each variable(-interaction), `auto.key = FALSE` is default setting. For `type = "blearner"` the argument has no effect at all.
...	additional arguments passed to `lattice::barchart`.
row.names	NULL or a character vector giving the row names for the data frame. Missing values are not allowed.
optional	logical. If TRUE, setting row names and converting column names (to syntactic names: see make.names) is optional.

Details

This function extracts the in-bag risk reductions per boosting step of a fitted `mboost` model and accumulates it individually for each base-learner contained in the model. This quantifies the individual contribution to risk reduction of each base-learner and can thus be used to compare the importance of different base-learners or variables in the model. Starting from offset only, in each boosting step risk reduction is computed as the difference between in-bag risk of the current and the previous model and is accounted for the base-learner selected in the particular step.

The results can be plotted in a bar plot either for the base-learners, or the variables contained in the model. The bars are ordered according to variable importance. If their number exceeds `nbars` the least important are summarized as "other". If bars are plotted per variable, all base-learners containing the same variable will be accumulated in a stacked bar. This is of use for models including for example seperate base-learners for the linear and non-linear part of a covariate effect (see ?bbs option center=TRUE). However, variable interactions are treated as individual variables, as their desired handling might depend on context.

As a comparison the selection frequencies are added to the respective base-learner labels in the plot (rounded to three digits). For stacked bars they are ordered accordingly.

Value

An object of class `varimp` with available `plot` and `as.data.frame` methods.

Converting a `varimp` object results in a `data.frame` containing the risk reductions, selection frequencies and the corresponding base-learner and variable names as ordered `factors` (ordered according to their particular importance).
