

# Package ‘phyloregion’

May 1, 2021

**Type** Package

**Title** Biogeographic Regionalization and Macroecology

**Version** 1.0.6

**Description** Computational infrastructure for biogeography, community ecology, and biodiversity conservation (Daru et al. 2020) <doi:10.1111/2041-210X.13478>. It is based on the methods described in Daru et al. (2020) <doi:10.1038/s41467-020-15921-6>. The original conceptual work is described in Daru et al. (2017) <doi:10.1016/j.tree.2017.08.013> on patterns and processes of biogeographical regionalization. Additionally, the package contains fast and efficient functions to compute more standard conservation measures such as phylogenetic diversity, phylogenetic endemism, evolutionary distinctiveness and global endangerment, as well as compositional turnover (e.g., beta diversity).

**Imports** ape, phangorn, Matrix, betapart, parallel, methods, raster, colorspace, vegan, sp, igraph, clustMixType, dismo, randomForest, rgeos, rgdal

**Suggests** tinytest, knitr, rmarkdown, mapproj, survival, gbm, rJava

**VignetteBuilder** knitr

**URL** <https://github.com/darunabas/phyloregion>,  
<https://darunabas.github.io/phyloregion/index.html>

**BugReports** <https://github.com/darunabas/phyloregion/issues>

**License** AGPL-3

**Encoding** UTF-8

**RoxygenNote** 7.1.1

**NeedsCompilation** no

**Depends** R (>= 4.0.0)

**Author** Barnabas H. Daru [aut, cre, cph]

## Description

This document describes the phyloregion package for the R software. phyloregion is a computational infrastructure for biogeographic regionalization (the classification of geographical areas in terms of their biotas) and spatial conservation in the R scientific computing environment. Previous analyses of biogeographical regionalization were either focused on smaller datasets or slower particularly when the number of species or geographic scale is very large. With macroecological datasets of ever increasing size and complexity, phyloregion offers the possibility of handling and executing large scale biogeographic regionalization efficiently and with extreme speed. It also allows fast and efficient analysis of more standard conservation measures such as phylogenetic diversity, phylogenetic endemism, evolutionary distinctiveness and global endangerment. phyloregion can run on any operating system (Mac, Linux, Windows or even high performance computing cluster) with R 3.6.0 (or higher) installed.

## How to cite phyloregion

The original implementation of phyloregion is described in:

- Daru B.H., Karunarathne, P. & Schliep, K. (2020) phyloregion: R package for biogeographic regionalization and spatial conservation. *bioRxiv* 2020.02.12.945691 doi: 10.1101/2020.02.12.945691

It is based on the method described in:

- Daru, B.H., Farooq, H., Antonelli, A. & Faurby, S. (2020) Endemism patterns are scale dependent. *Coming soon.*

The original conceptual is described in:

- Daru, B.H., Elliott, T.L., Park, D.S. & Davies, T.J. (2017) Understanding the processes underpinning patterns of phylogenetic regionalization. *Trends in Ecology and Evolution* **32**: 845-860.

## Feedback

If you have any questions, suggestions or issues regarding the package, please add them to [GitHub issues](#)

## Installation

phyloregion is an open-source and free package hosted on [GitHub](#). You will need to install the devtools package. In R, type:

```
if (!requireNamespace("devtools", quietly = TRUE)) install.packages("devtools")
```

Then:

```
devtools::install_github("darunabas/phyloregion")
```

Load the phyloregion package:

```
library(phyloregion)
```

## Acknowledgments

Barnabas Daru thanks Texas A&M University-Corpus Christi for financial and logistic support.

## Author(s)

Barnabas H. Daru, Piyal Karunaratne, Klaus Schliep

africa

*Plants of southern Africa*

## Description

This dataset consists of a dated phylogeny of the woody plant species of southern Africa along with their geographical distributions. The dataset comes from a study that maps tree diversity hotspots in southern Africa (Daru et al. 2015). The study mapped five types of diversity hotspots including species richness (SR), phylogenetic diversity (PD), phylogenetic endemism (PE), species weighted endemism (CWE), and evolutionary distinctiveness and global endangerment (EDGE). The results revealed large spatial incongruence between biodiversity indices, resulting in unequal representation of PD, SR, PE, CWE and EDGE in hotspots and currently protected areas, suggesting that an integrative approach which considers multiple facets of biodiversity is needed to maximise the conservation of tree diversity in southern Africa. Specifically for this package, we arranged the dataset into four components: “comm”, “polys”, “phylo”, “mat”, “IUCN”.

## Details

- comm: This is a sparse community composition matrix of each species presences/absences within  $50 \times 50$  km grid cells. A sparse matrix is a matrix with a high proportion of zero entries (Duff 1977), of which only the non-zero entries are stored and used for downstream analysis.
- polys: These are the grid cells covering the geographic extent of study area. These can be created using the function `fishnet`. The polys object is of class `SpatialPolygonsDataFrame` and has a column labeled “grids”, with the grid identities.
- phylo: This corresponds to the phylogenetic tree which was estimated using Bayesian analysis of 1,400 species and 1,633 bp of chloroplast DNA sequences derived from a combination of *matK* and *rbcLa*, assuming an uncorrelated relaxed molecular clock model, using the program BEAST v.1.7.5 (Drummond & Rambaut, 2007). Branch lengths were calibrated in millions of years using a Bayesian MCMC approach by enforcing topological constraints assuming APG III backbone from Phylomatic v.3 (Webb & Donoghue, 2005) and 18 fossil calibration points from Bell et al. (2010).
- mat: This is a distance matrix of phylogenetic beta diversity between all grid cells at the  $50 \times 50$  km scale.
- IUCN: This is a data frame of IUCN conservation status of each woody species (LC, NT, VU, EN, CR). This is useful for analysis of Evolutionary Distinctiveness and Global Endangerment using the function `EDGE`.

## Examples

```
data(africa)
names(africa)

library(raster)
library(ape)
plot(africa$polys)
plot(africa$phylo)
```

**arc\_labels**

*Add arc labels to plotted phylogeny*

## Description

Add arc labels to plotted phylogeny

## Usage

```
arc_labels(phy, tips, ...)

## Default S3 method:
arc_labels(
  phy = NULL,
  tips,
  text,
  plot_singletons = TRUE,
  ln.offset = 1.02,
  lab.offset = 1.06,
  cex = 1,
  orientation = "horizontal",
  ...
)
```

## Arguments

phy	An object of class phylo.
tips	A character vector (or a list) with names of the tips that belong to the clade or group. If multiple groups are to be plotted, tips must be given in the form of a list.
...	Further arguments passed to or from other methods.
text	Desired clade label.
plot_singletons	Logical. If TRUE (default), adds arcs (and labels) to single tip lineages. If FALSE, no arc or labels will be plotted over that tip..
ln.offset	Line offset (as a function of total tree height)
lab.offset	Label offset.
cex	Character expansion
orientation	Orientation of the text. Can be “vertical”, “horizontal”, or “curved”.

## Value

NULL

## Examples

---

beta_core	<i>Taxonomic (non-phylogenetic) beta diversity</i>
-----------	--

---

## Description

Data are assumed to be presence / absence (0 / 1) and all values greater zero are assumed to reflect presence.

## Usage

```
beta_core(x)  
beta_diss(x, index.family = "sorensen")
```

## Arguments

x an object of class Matrix, where rows are sites and columns are species.  
index.family family of dissimilarity indices, partial match of "sorensen" or "jaccard".

## Details

beta\_core is helper function to compute the basic quantities needed for computing the "sorensen" or "jaccard" index.

## Value

beta\_core returns an object of class beta\_diss like the [betapart.core](#) function. This object can be called by [beta.pair](#) or [beta.multi](#).  
beta\_diss returns a list with three dissimilarity matrices. See [beta.pair](#) for details.

## Author(s)

Klaus Schliep

## See Also

[betapart.core](#), [betapart](#), [phylobeta](#)

## Examples

```
data(africa)
x <- africa$comm
bc <- beta_core(x)
beta_sorensen <- beta_diss(x)
```

**choropleth***Bin values***Description**

`choropleth` discretizes the values of a quantity for mapping.

**Usage**

```
choropleth(x, k = 10, breaks = "quantile", min = NULL, max = NULL)
```

**Arguments**

<code>x</code>	Vector of values to discretize.
<code>k</code>	Numeric, the desired number of bins to discretize.
<code>breaks</code>	one of “equal”, “pretty”, “jenks”, “quantile” or numeric vector with the actual breaks by specifying the minimum ( <code>min</code> ) and maximum ( <code>max</code> ) bounds.
<code>min</code>	the minima of the lowest bound of the break.
<code>max</code>	the maxima of the upper bound of the break

**Value**

a vector with the discretized values.

**Author(s)**

Barnabas H. Daru <[darunabas@gmail.com](mailto:darunabas@gmail.com)>

**See Also**

[coldspots](#)

**Examples**

```
library(sp)
s <- readRDS(system.file("nigeria/SR_Naija.rds", package = "phyloregion"))
k <- 10
COLOUR <- hcl.colors(k, "RdYlBu")
y <- choropleth(s$SR, k)

plot(s$SR, y)
## To plot and color according to some metric:
plot(s, col = COLOUR[y])
```

---

**coldspots***Computes biodiversity coldspots and hotspots*

---

## Description

coldspots and hotspots map areas or grid cells with lowest or highest values, respectively, of a biodiversity metric e.g. species richness, species endemism or degree of threat.

## Usage

```
coldspots(x, prob = 2.5, na.rm = TRUE, ...)
```

```
hotspots(x, prob = 2.5, na.rm = TRUE, ...)
```

## Arguments

x	a vector on which to compute coldspots
prob	The threshold quantile for representing the lowest (coldspots) or highest (hotspots) proportion of biodiversity in an area. By default, the threshold is set to prob = 2.5 percent.
na.rm	logical; if true, any NA and NaN's are removed from x before the quantiles are computed.
...	Further arguments passed to or from other methods.

## Value

A vector of integers of 1s and 0s with 1 corresponding to the coldspots or hotspots

## Author(s)

Barnabas H. Daru <[darunabas@gmail.com](mailto:darunabas@gmail.com)>

Endm <- weighted_endemism(africa$comm)
C <- coldspots(Endm) # coldspots
H <- hotspots(Endm) # hotspots

## Merge endemism values to shapefile of grid cells.
DF <- data.frame(grids=names(C), cold=C, hot=H)
m <- merge(africa$polys, DF, by = "grids", all = TRUE)

plot(africa$polys, border = "grey", col = "lightgrey",
      main = "Weighted Endemism Hotspots and Coldspots")
plot(m[(m@data$cold == 1), ], col = "blue", add = TRUE, border = NA)
plot(m[(m@data$hot == 1), ], col = "red", add = TRUE, border = NA)
legend("bottomleft", fill = c("blue", "red", "yellow", "green"),
       legend = c("coldspots", "hotspots"), bty = "n", inset = .092)

```

**collapse\_range**

*Collapse nodes and ranges based on divergence times*

## Description

This function collapses nodes and geographic ranges based on species' divergence times at various time depths.

## Usage

```

collapse_range(
  x,
  tree,
  n,
  species = "species",
  grids = "grids",
  format = "wide"
)

```

## Arguments

<b>x</b>	A community matrix or data frame.
<b>tree</b>	A phylogenetic tree.
<b>n</b>	Time depth to slice the phylogenetic tree (often in millions of years for dated trees).
<b>species</b>	If format = “long” (the default), the column with the species name.

grids	The column with the sites or grids if <code>format = "long"</code> .
format	Format of the community composition data: “long” or “wide” with species as columns and sites as rows.

**Value**

Two community data frames: the collapsed community data and original community data

**References**

Daru, B.H., Farooq, H., Antonelli, A. & Faurby, S. (2020) Endemism patterns are scale dependent. *Nature Communications* **11**: 2115.

**Examples**

```
library(ape)
tr1 <- read.tree(text = "((a:2,(b:1,c:1):1):1,d:3):1,e:4;")
com <- matrix(c(1,0,1,1,0,0,
                 1,0,0,1,1,0,
                 1,1,1,1,1,1,
                 1,0,1,1,0,1,
                 0,0,0,1,1,0), 6, 5,
                 dimnames=list(paste0("g",1:6), tr1$tip.label))

collapse_range(com, tr1, n=1)
```

**Description**

Generates a sparse community matrix as input for clustering regions based on the similarity of functional traits across species.

**Usage**

```
counts(x, trait, cut = NULL, phy = NULL, bin = 10, na.rm = FALSE)
```

**Arguments**

x	A community data in long format with one column representing sites labeled “grids” and another column representing species labeled “species”.
trait	A data frame or matrix object with the first column labeled “species” containing the taxonomic groups to be evaluated whereas the remaining columns have the various functional traits. The variables must be a mix of numeric and categorical values.
cut	The slice time.

phy	is a dated phylogenetic tree with branch lengths stored as a phylo object (as in the ape package).
bin	The desired number of clusters or bins.
na.rm	Logical, whether NA values should be removed or not.

**Value**

Function returns a community data frame that captures the count of each species based on its cluster membership.

**Description**

This function calculates EDGE by combining evolutionary distinctiveness (ED; i.e., phylogenetic isolation of a species) with global endangerment (GE) status as defined by the International Union for Conservation of Nature (IUCN).

**Usage**

```
EDGE(x, phy, Redlist = "Redlist", species = "species", ...)
```

**Arguments**

x	a data.frame
phy	a phylogenetic tree (object of class phylo).
Redlist	column in the data frame with the IUCN ranks: LC, NT, VU, EN, CR, and EX.
species	data frame column specifying the taxon
...	Further arguments passed to or from other methods.

**Details**

EDGE is calculated as:

$$\log(1 + ED) + GE * \log(2)$$

where *ED* represents the evolutionary distinctiveness score of each species (function *evol\_distinct*), i.e. the degree of phylogenetic isolation, and combining it with *GE*, global endangerment from IUCN conservation threat categories. *GE* is calculated as the expected probability of extinction over 100 years of each taxon in the phylogeny (Redding & Mooers, 2006), scaled as follows: least concern = 0.001, near threatened and conservation dependent = 0.01, vulnerable = 0.1, endangered = 0.67, and critically endangered = 0.999.

**Value**

Returns a dataframe of EDGE scores

**Author(s)**

Barnabas H. Daru

**References**

- Redding, D.W., & Mooers, A.Q. (2006) Incorporating evolutionary measures into conservation prioritization. *Conservation Biology* **20**: 1670–1678.
- Isaac, N.J., Turvey, S.T., Collen, B., Waterman, C. & Baillie, J.E. (2007) Mammals on the EDGE: conservation priorities based on threat and phylogeny. *PLoS ONE* **2**: e296.

**Examples**

```
data(africa)
y <- EDGE(x=africa$IUCN, phy=africa$phylo, Redlist="IUCN", species="Species")
```

evol_distinct	<i>Species' evolutionary distinctiveness</i>
---------------	--

**Description**

Calculates evolutionary distinctiveness measures for a suite of species by: a) equal splits (Redding and Mooers 2006) b) fair proportions (Isaac et al., 2007). This a new implementation of the picante function evol.distinct however allowing multifurcations and can be orders of magnitude faster.

**Usage**

```
evol_distinct(
  tree,
  type = c("equal.splits", "fair.proportion"),
  scale = FALSE,
  use.branch.lengths = TRUE,
  ...
)
```

**Arguments**

- |                    |  |
|--------------------|--|
| tree               | an object of class phylo.  |
| type               | a) equal splits (Redding and Mooers 2006) or b) fair proportions (Isaac et al., 2007)  |
| scale              | The scale option refers to whether or not the phylogeny should be scaled to a depth of 1 or, in the case of an ultrametric tree, scaled such that branch lengths are relative. |
| use.branch.lengths | If use.branch.lengths=FALSE, then all branch lengths are changed to 1.   |
| ...                | Further arguments passed to or from other methods.   |

**Value**

a named vector with species scores.

**Author(s)**

Klaus Schliep

**Examples**

```
tree <- ape::rcoal(10)
evol_distinct(tree)
evol_distinct(tree, type = "fair.proportion")
```

**fishnet**

*Create a fishnet of regular grids*

**Description**

The `fishnet` function creates a regular grid of locations covering the study area at various grain sizes.

**Usage**

```
fishnet(mask, res = 0.5, type = "square")
```

**Arguments**

- |                   |  |
|-------------------|--|
| <code>mask</code> | a polygon shapefile covering the boundary of the survey region.                                      |
| <code>res</code>  | the grain size of the grid cells in decimal degrees (default).                                       |
| <code>type</code> | the type of grid cell; either “square” (default) for square grids, or “hexagon” for hexagonal grids. |

**Value**

A spatial polygon object of equal area grid cells covering the defined area.

## References

Phillips, S.J., Anderson, R.P. & Schapire, R.E. (2006) Maximum entropy modeling of species geographic distributions. *Ecological Modelling* **190**: 231-259.

## Examples

```
file <- system.file("nigeria/nigeria.rds", package="phyloregion")
d <- readRDS(file)
d1 <- fishnet(d, res = 0.75)
```

---

get\_clades

*Get descendant nodes of phylogeny at a given time depth*

---

## Description

get\_clades returns the tips that descend from a given node or time depth on a dated phylogenetic tree.

## Usage

```
get_clades(tree, cut = NULL, k = NULL)
```

## Arguments

tree	is a dated phylogenetic tree with branch lengths stored as a phylo object (as in the ape package).
cut	the slice time
k	number of slices

## Value

A list of descendants

## References

Schliep, K.P. (2010) phangorn: phylogenetic analysis in R. *Bioinformatics* **27**: 592–593.

## Examples

```
require(ape)
data(bird.orders)
plot(bird.orders)
axisPhylo(side = 1)
abline(v=28-23) # the root is here at 28
get_clades(bird.orders, 23)
```

<code>hexcols</code>	<i>Generate diverging colors in HCL colour space.</i>
----------------------	---

## Description

A function to generate colors in Hue-Chroma-Luminance colour scheme for mapping phyloregions.

## Usage

```
hexcols(x)
```

## Arguments

<code>x</code>	An object of class <code>metaMDS</code>
----------------	---

## Value

A range of discrete colors differentiating between phyloregions in terms of their shared relationships.

## Author(s)

Barnabas H. Daru <[darunabas@gmail.com](mailto:darunabas@gmail.com)>

## Examples

```
library(vegan)
data(dune)
c1 <- metaMDS(dune, trace = 0)
hexcols(c1)
plot(c1$points, pch = 21, cex = 7, bg = hexcols(c1), las = 1)
```

<code>indicators</code>	<i>Top driving species in phyloregions</i>
-------------------------	--

## Description

This function applies a KL-divergence approach to a list of indicator species in phyloregions.

## Usage

```
indicators(
  theta,
  top_indicators = 5,
  method = c("poisson", "bernoulli"),
  options = c("min", "max"),
  shared = FALSE
)
```

## Arguments

theta	A matrix or data.frame of cluster probability distributions from a topics modeling.
top_indicators	Integer to obtain the top driving species in clusters.
method	The model assumption for KL divergence measurement. Available choices are "poisson" (default) and "bernoulli".
options	Option "min" selects species that maximize the minimum KL divergence of a phyloregion vs all other phyloregions. Option "max" selects species that maximize the maximum KL divergence of a phyloregion against all other phyloregions.
shared	Logical if TRUE, lists top species driving patterns in more than one phyloregion.

## Value

A list of top indicator species and their indicator values

## Examples

```
data(africa)
indsp <- indicators(africa$theta, top_indicators = 5,
                      options = "max", method = "poisson")
```

long2sparse

*Conversion of community data*

## Description

These functions convert a community data to compressed sparse matrix, dense matrix and long format (e.g. species records).

## Usage

```
long2sparse(x, grids = "grids", species = "species")

sparse2long(x)

dense2sparse(x)

sparse2dense(x)

long2dense(x)

dense2long(x)
```

**Arguments**

<b>x</b>	A community data which one wants to transform
<b>grids</b>	column name of the column containing grid cells
<b>species</b>	column name of the column containing the species / taxa names

**Value**

A compressed sparse community matrix of sites by species

**Examples**

```
data(africa)
africa$comm[1:5, 1:20]
long <- sparse2long(africa$comm)
long[1:5, ]
sparse <- long2sparse(long)
all.equal(africa$comm, sparse)

dense_comm <- matrix(c(1,0,1,1,0,0,
                      1,0,0,1,1,0,
                      1,1,1,1,1,1,
                      0,0,1,1,0,1), 6, 4,
                      dimnames=list(paste0("g",1:6), paste0("sp", 1:4)))
dense_comm
sparse_comm <- dense2sparse(dense_comm)
sparse_comm
sparse2long(sparse_comm)
```

**map\_trait**

*Map species' trait values in geographic space*

**Description**

`map_trait` add species trait values to species distribution in geographic space.

**Usage**

```
map_trait(x, trait, FUN = sum, shp = NULL, ...)
```

**Arguments**

<b>x</b>	A community data object - a vector (with names matching trait data) or a data.frame or matrix (with column names matching names in trait data)
<b>trait</b>	A data.frame of species traits with a column of species names matching species names in the community data, and another column with the trait values.

FUN	The function used to aggregate species trait values in geographic space. By default, if FUN = sum, the sum of all species traits per area or grid cell is calculated.
shp	a polygon shapefile of grid cells.
...	Further arguments passed to or from other methods.

**Value**

A data frame of species traits by site.

**Author(s)**

Barnabas H. Daru <darunabas@gmail.com>

**Examples**

```
data(africa)
x <- EDGE(africa$IUCN, africa$phylo, Redlist = "IUCN", species="Species")
y <- map_trait(africa$comm, x, FUN = sd, shp=africa$polys)

plot_swatch(y, y$traits,
            col = hcl.colors(n=20, palette = "Blue-Red 3", rev=FALSE))
```

**match\_phylo\_comm**

*Match taxa and in phylogeny and community matrix*

**Description**

match\_phylo\_comm compares taxa (species, labels, tips) present in a phylogeny with a community matrix. Pruning, sorting and trying to add missing species on genus level if possible to match in subsequent analysis.

**Usage**

```
match_phylo_comm(phy, comm, delete_empty_rows = TRUE)
```

**Arguments**

phy	A phylogeny
comm	A (sparse) community data matrix
delete_empty_rows	delete rows with no observation

**Details**

Based on the function of the same name in picante but allows sparse matrices and with taxa addition.

**Value**

A list containing the following elements, pruned and sorted to match one another:

<code>phy</code>	A phylogeny object of class <code>phylo</code>
<code>comm</code>	A (sparse) community data matrix

**Examples**

```
data(africa)
tree <- africa$phylo
x <- africa$comm

subphy <- match_phylo_comm(tree, x)$phy
submat <- match_phylo_comm(tree, x)$com
```

**mean\_dist**

*Mean distance matrix from a set of distance matrices*

**Description**

This function generates the mean pairwise distance matrix from a set many pairwise distance matrices. Note: all matrices should be of the same dimension.

**Usage**

```
mean_dist(files, trace = 1, ...)
```

**Arguments**

<code>files</code>	list of pairwise distance matrices stored as CSVs or .rds with the same dimensions.
<code>trace</code>	Trace the function; trace = 2 or higher will be more voluminous.
<code>...</code>	Further arguments passed to or from other methods.

**Value**

average distance matrix

---

nodepie	<i>Label phylogenetic nodes using pie</i>
---------	---

---

## Description

Label phylogenetic nodes using pie

## Usage

```
nodepie(  
  pie,  
  radius = 2,  
  pie_control = list(),  
  legend = FALSE,  
  col = hcl.colors(5),  
  ...  
)
```

## Arguments

pie	Estimates from ancestral character reconstruction
radius	Radius of the pie
pie_control	The list of control parameters to be passed into the add.pie function.
legend	Logical, whether to add a legend or not.
col	List of colors for the pies.
...	Further arguments passed to or from other methods.

## Value

Returns no value, just add color pies on phylogenetic nodes!

---

optimal_phyloregion	<i>Determine optimal number of clusters</i>
---------------------	---

---

## Description

This function divides the hierarchical dendrogram into meaningful clusters ("phyloregions"), based on the 'elbow' or 'knee' of an evaluation graph that corresponds to the point of optimal curvature.

## Usage

```
optimal_phyloregion(x, method = "average", k = 20)
```

## Arguments

x	a numeric matrix, data frame or “dist” object.
method	the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of “ward.D”, “ward.D2”, “single”, “complete”, “average” (= UPGMA), “mcquitty” (= WPGMA), “median” (= WPGMC) or “centroid” (= UPGMC).
k	numeric, the upper bound of the number of clusters to compute. DEFAULT: 20 or the number of observations (if less than 20).

## Value

a list containing the following as returned from the GMD package (Zhao et al. 2011):

- k: optimal number of clusters (bioregions)
- totbss: total between-cluster sum-of-square
- tss: total sum of squares of the data
- ev: explained variance given k

## References

- Salvador, S. & Chan, P. (2004) *Determining the number of clusters/segments in hierarchical clustering/segmentation algorithms*. - Zhao, X., Valen, E., Parker, B.J. & Sandelin, A. (2011) Systematic clustering of transcription start site landscapes. *PLoS ONE* **6**: e23409.

## Examples

```
data(africa)
tree <- africa$phylo
bc <- beta_diss(africa$comm)
(d <- optimal_phyloregion(bc[[1]]))
plot(d$df$k, d$df$ev, ylab = "Explained variances",
     xlab = "Number of clusters")
lines(d$df$k[order(d$df$k)], d$df$ev[order(d$df$k)], pch = 1)
points(d$optimal$k, d$optimal$ev, pch = 21, bg = "red", cex = 3)
points(d$optimal$k, d$optimal$ev, pch = 21, bg = "red", type = "h")
```

## Description

PD calculates Faith’s (1992) phylogenetic diversity.

**Usage**

```
PD(x, phy)
```

**Arguments**

- |     |   |
|-----|---|
| x   | a community matrix, i.e. an object of class matrix or Matrix. |
| phy | a phylogenetic tree (object of class phylo).                  |

**Value**

a vector with the PD for all samples.

**References**

Faith, D.P. (1992) Conservation evaluation and phylogenetic diversity. *Biological Conservation* **61**: 1–10.

**See Also**

`read.community` `read.tree` `phylobeta_core`

**Examples**

```
library(ape)
library(Matrix)
tree <- read.tree(text = "((t1:1,t2:1)N2:1,(t3:1,t4:1)N3:1)N1;")
com <- sparseMatrix(c(1,3,4,1,4,5,1,2,3,4,5,6,3,4,6),
                     c(1,1,1,2,2,2,3,3,3,3,3,3,4,4,4), x=1,
                     dimnames = list(paste0("g", 1:6), tree$tip.label))

PD(com, tree)
```

**Description**

This function computes the standard effect size of PD by correcting for changes in species richness. The novelty of this function is its ability to utilize sparse community matrix making it possible to efficiently randomize very large community matrices spanning thousands of taxa and sites.

**Usage**

```
PD_ses(x, phy, model = c("tipshuffle", "rowwise", "colwise"), reps = 1000, ...)
```

### Arguments

x	a (sparse) community matrix, i.e. an object of class matrix or Matrix.
phy	a phylogenetic tree (object of class phylo).
model	The null model for separating patterns from processes and for contrasting against alternative hypotheses. Available null models include: <ul style="list-style-type: none"> <li>“tipshuffle”: shuffles tip labels multiple times.</li> <li>“rowwise”: shuffles sites (i.e., varying richness) and keeping species occurrence frequency constant.</li> <li>“colwise”: shuffles species occurrence frequency and keeping site richness constant.</li> </ul>
reps	Number of replications.
...	Further arguments passed to or from other methods.

### Value

A data frame of results for each community or grid cell

- grids: Site identity
- richness: Number of taxa in community
- PD\_obs: Observed PD in community
- pd\_rand\_mean: Mean PD in null communities
- pd\_rand\_sd: Standard deviation of PD in null communities
- pd\_obs\_rank: Rank of observed PD vs. null communities
- pd\_obs\_z: Standardized effect size of PD vs. null communities =  $(PD_{obs} - pd_{rand,mean}) / pd_{rand,sd}$
- pd\_obs\_p: P-value (quantile) of observed PD vs. null communities =  $mpd_{obs,rank}/iter + 1$
- reps: Number of replicates

### Examples

```
library(ape)
library(Matrix)
tree <- read.tree(text = "((t1:1,t2:1)N2:1,(t3:1,t4:1)N3:1)N1;")
com <- sparseMatrix(c(1,3,4,1,4,5,1,2,3,4,5,6,3,4,6),
                     c(1,1,1,2,2,2,3,3,3,3,3,4,4,4), x=1,
                     dimnames = list(paste0("g", 1:6), tree$tip.label))

PD_ses(com, tree, model="rowwise")
```

---

phylobeta_core	<i>Phylogenetic beta diversity</i>
----------------	------------------------------------

---

**Description**

`phylobeta_core` computes efficiently for large community matrices and trees the necessary quantities used by the betapart package to compute pairwise and multiple-site phylogenetic dissimilarities.

**Usage**

```
phylobeta_core(x, phy)
phylobeta(x, phy, index.family = "sorensen")
```

**Arguments**

<code>x</code>	an object of class <code>Matrix</code> or <code>matrix</code>
<code>phy</code>	a phylogenetic tree (object of class <code>phylo</code> )
<code>index.family</code>	family of dissimilarity indices, partial match of "sorensen" or "jaccard".

**Value**

`phylobeta_core` returns an object of class "phylo.betapart", see [phylo.betapart.core](#) for details. This object can be called by [phylo.beta.pair](#) or [phylo.beta.multi](#).

`phylobeta` returns a list with three phylogenetic dissimilarity matrices. See [phylo.beta.pair](#) for details.

**Author(s)**

Klaus Schliep

**phylobeta\_ses***Phylogenetic beta diversity standardized for species beta diversity*

---

## Description

This function computes the standard effect size of phylogenetic beta diversity by correcting for changes in species beta diversity. The novelty of this function is its ability to utilize sparse community matrix making it possible to efficiently randomize very large community matrices spanning thousands of taxa and sites.

## Usage

```
phylobeta_ses(
  x,
  phy,
  index.family = "simpson",
  model = c("tipshuffle", "rowwise", "colwise"),
  reps = 1000,
  ...
)
```

## Arguments

- |                           |  |
|---------------------------|--|
| <code>x</code>            | a (sparse) community matrix, i.e., an object of class matrix or Matrix.  |
| <code>phy</code>          | a phylogenetic tree (object of class phylo).   |
| <code>index.family</code> | the family of dissimilarity indices including “simpson”, “sorensen” and “jaccard”.   |
| <code>model</code>        | The null model for separating patterns from processes and for contrasting against alternative hypotheses. Available null models include: <ul style="list-style-type: none"> <li>• “tipshuffle”: shuffles phylogenetic tip labels multiple times.</li> <li>• “rowwise”: shuffles sites (i.e., varying richness) and keeping species occurrence frequency constant.</li> <li>• “colwise”: shuffles species occurrence frequency and keeping site richness constant.</li> </ul> |
| <code>reps</code>         | Number of replications.  |
| <code>...</code>          | Further arguments passed to or from other methods.   |

## Value

A data frame of results for each community or grid cell

- `phylobeta_obs`: Observed phylobeta in community
- `phylobeta_rand_mean`: Mean phylobeta in null communities
- `phylobeta_rand_sd`: Standard deviation of phylobeta in null communities

- phylobeta\_obs\_z: Standardized effect size of phylobeta vs. null communities =  $(phylobeta_{obs} - phylobeta_{mean})/phylobeta_{sd}$
- reps: Number of replicates

## References

```
library(ape)
library(Matrix)
tree <- read.tree(text = "((t1:1,t2:1)N2:1,(t3:1,t4:1)N3:1)N1;")
com <- sparseMatrix(c(1,3,4,1,4,5,1,2,3,4,5,6,3,4,6),
c(1,1,1,2,2,2,3,3,3,3,3,4,4,4),x=1,
dimnames = list(paste0("g", 1:6), tree$tip.label))

phylobeta_ses(com, tree, model="rowwise")
```

**phylobuilder**

*Create a subtree with largest overlap from a species list.*

## Description

phylobuilder creates a subtree with largest overlap from a species list. If species in the species list are not already in the tip label, species will be added at the most recent common ancestor at the genus or family level when possible.

## Usage

```
phylobuilder(species, tree, extract = TRUE)
```

## Arguments

species	A vector or matrix containing a species list
tree	a phylogenetic tree (object of class phylo)
extract	extract the species in the list after trying to add missing labels to the tree. If FALSE phylobuilder adds only the taxa in the list.

## Value

phylobuilder returns a phylogenetic tree, i.e. an object of class phylo.

## See Also

[add.tips](#), [label2table](#), [stripLabel](#)

## Examples

```

library(ape)
txt <- "((((Panthera_leo,Panthera_pardus), Panthera_onca),(Panthera_uncia,
(Panthera_tigris_altaica, Panthera_tigris_amoyensis)))Panthera)Felidae,
(((((Canis_lupus,Canis_lupus_familiaris),Canis_latrans),Canis_anthus),
Canis_aureus),Lycaon_pictus),(Canis_adustus,Canis_mesomelas))Canis
Canidae)Carnivora;"
txt <- gsub("[[:space:]]", "", txt)
cats_and_dogs <- read.tree(text=txt)
plot(cats_and_dogs, node.depth=2, direction="downwards")
nodelabels(cats_and_dogs$node.label, frame="none", adj = c(0.5, 0))

tree <- drop.tip(cats_and_dogs, c("Panthera_uncia", "Lycaon_pictus"),
collapse.singles=FALSE)

dogs <- c("Canis_lupus", "Canis_lupus_familiaris", "Canis_latrans",
"Canis_anthus", "Canis_aureus", "Lycaon_pictus", "Canis_adustus",
"Canis_mesomelas")

# try to extract tree with all 'dogs'
t1 <- phylobuilder(dogs, tree)
plot(t1, direction="downwards")
attr(t1, "species_list")

# providing extra information ("Family", "Order", ...) can help
sp <- data.frame(Order = c("Carnivora", "Carnivora", "Carnivora"),
Family = c("Felidae", "Canidae", "Canidae"),
Genus = c("Panthera", "Lycaon", "Vulpes"),
Species = c("uncia", "pictus", "vulpes"),
Common_name = c("Snow leopard", "Africa wild dog", "Red fox"))
sp
# Now we just add some species
t2 <- phylobuilder(sp, tree, extract=FALSE)
plot(t2, direction="downwards")
attr(t2, "species_list")

```

phyloregion

*Calculate evolutionary distinctiveness of phyloregions*

## Description

This function estimates evolutionary distinctiveness of each phyloregion by computing the mean value of phylogenetic beta diversity between a focal phyloregion and all other phyloregions in the study area.

## Usage

```

phyloregion(x, k = 10, method = "average", shp = NULL, ...)
infomap(x, shp = NULL, ...)

```

**Arguments**

x	A distance matrix
k	The desired number of phyloregions, often as determined by <code>optimal_phyloregion</code> .
method	the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of “ward.D”, “ward.D2”, “single”, “complete”, “average” (= UPGMA), “mcquitty” (= WPGMA), “median” (= WPGMC) or “centroid” (= UPGMC).
shp	a polygon shapefile of grid cells.
...	Further arguments passed to or from other methods.

**Value**

An object of class `phyloregion` containing

- a data frame membership with columns grids and cluster
- k the number of clusters and additionally there can be an shape file and other objects. This representation may still change.

---

<code>phylo_endemism</code>	<i>Phylogenetic Endemism</i>
-----------------------------	------------------------------

---

## Description

Calculates phylogenetic endemism (sum of 'unique' branch lengths) of multiple ecological samples.

## Usage

```
phylo_endemism(x, phy, weighted = TRUE)
```

## Arguments

- |                       |   |
|-----------------------|---|
| <code>x</code>        | is the community data given as a data.frame or matrix with species/OTUs as columns and samples/sites as rows (like in the vegan package). Columns are labeled with the names of the species/OTUs. Rows are labelled with the names of the samples/sites. Data can be either abundance or incidence (0/1). Column labels must match tip labels in the phylogenetic tree exactly! |
| <code>phy</code>      | a (rooted) phylogenetic tree ( <code>phylo</code> ) with branch lengths   |
| <code>weighted</code> | is a logical indicating whether weighted endemism (default) or strict endemism should be calculated.  |

## Details

Takes a community data table and a (rooted) phylogenetic tree (with branch lengths) and calculates either strict or weighted endemism in Phylogenetic Diversity (PD). Strict endemism equates to the total amount of branch length found only in the sample/s and is described by Faith et al. (2004) as PD-endemism. Weighted endemism calculates the "spatial uniqueness" of each branch in the tree by taking the reciprocal of its range, multiplying by branch length and summing for all branch lengths present at a sample/site. Range is calculated simply as the total number of samples/sites at which the branch is present. This latter approach is described by Rosauer et al. (2009) as Phylogenetic endemism.

## Value

`phylo_endemism` returns a vector of phylogenetic endemism for each sample or site.

## References

pe <- phylo_endemism(africa$comm, africa$phylo)
plot(density(pe))
```

plot.phyloregion	<i>Visualize biogeographic patterns</i>
------------------	---

## Description

Visualize biogeographic patterns

## Usage

```
## S3 method for class 'phyloregion'
plot(x, shp = NULL, palette = "NMDS", col = NULL, ...)
plot_NMDS(x, ...)
text_NMDS(x, ...)
```

## Arguments

- x an object of class phyloregion from phyloregion
- shp a polygon shapefile of grid cells.
- palette name of the palette to generate colors from. The default, “NMDS”, allows display of phyloregions in multidimensional scaling color space matching the color vision of the human visual system. The name is matched to the list of available color palettes from the hcl.colors function in the grDevices package.
- col vector of colors of length equal to the number of phyloregions.
- ... arguments passed among methods.

## Value

No return value, called for plotting.

## Examples

```
data(africa)
tree <- africa$phylo
x <- africa$comm

subphy <- match_phylo_comm(tree, x)$phy
submat <- match_phylo_comm(tree, x)$com

pbc <- phylobeta(submat, subphy)
y <- phyloregion(pbc[[1]], shp=africa$polys)
```

```
plot_NMDS(y, cex=6)
text_NMDS(y, cex=2)
plot(y, cex=1, palette="NMDS")
plot(y, cex=1)
```

**plot\_pie***Visualize biogeographic patterns using pie charts***Description**

Visualize biogeographic patterns using pie charts

**Usage**

```
plot_pie(
  omega,
  shp,
  r = 1,
  col = hcl.colors(5),
  pie_control = list(),
  legend = FALSE,
  legend_pie = FALSE,
  ...
)
```

**Arguments**

<code>omega</code>	a matrix of phyloregion of probabilities of each species
<code>shp</code>	a polygon shapefile of grid cells with a column labeled “grids”.
<code>r</code>	Radius of the pie legend to be displayed
<code>col</code>	List of colors for the pies.
<code>pie_control</code>	The list of control parameters to be passed into the add.pie function.
<code>legend</code>	Logical, whether to plot a legend or not.
<code>legend_pie</code>	Legend for the pie plots.
<code>...</code>	Further arguments passed to or from other methods.

**Value**

Returns no value, just map color pies in geographic space!

**Examples**

```
data(africa)
K <- ncol(africa$omega)

COLRS <- phyloregion:::hue(K)
plot_pie(africa$omega, shp = africa$polys, col=COLRS)
```

---

<code>plot_structure</code>	<i>Visualize biogeographic patterns using structure plots</i>
-----------------------------	---

---

**Description**

Visualize biogeographic patterns using structure plots

**Usage**

```
plot_structure(omega, shp, by = NULL, col = hcl.colors(15), ...)
```

**Arguments**

<code>omega</code>	a matrix of phyloregion of probabilities of each species
<code>shp</code>	a polygon shapefile of grid cells with a column labeled “grids”.
<code>by</code>	Specification of the column used for grouping.
<code>col</code>	List of colors for the pies.
<code>...</code>	Further arguments passed to or from other methods.

**Value**

Returns no value, just visualize structure plot!

---

<code>plot_swatch</code>	<i>Plot shapefile polygons based on slot values</i>
--------------------------	---

---

**Description**

`plot_swatch` maps discretized values of a quantity using continuous color gradients.

**Usage**

```
plot_swatch(
  x,
  values = NULL,
  col = hcl.colors(n = 10, palette = "Blue-Red 3", rev = FALSE),
  key_label = "",
  leg = 10,
  lwd = 15,
  pos = "bottomleft",
  legend = TRUE,
  border = par("fg"),
  breaks = "quantile",
  min = NULL,
  max = NULL,
  ...
)
```

## Arguments

x	A data frame or object of the class SpatialPolygonsDataFrame
values	Variable in the SpatialPolygonsDataFrame for which to discretize the values of the quantity.
col	A vector of colors
key_label	label for the color key
leg	Numeric, length of the legend
lwd	numeric, line width of the legend.
pos	location to position the legend such as “bottomright”, “bottomleft”, “topleft”, and “topright”.
legend	logical indicating whether to add a legend to the map.
border	plot polygons in SpatialPolygons object
breaks	one of “equal”, “pretty”, “jenks”, “quantile” or numeric with the actual breaks by specifying the minimum ( <code>min</code> ) and maximum ( <code>max</code> ) bounds.
min	the minima of the lowest bound of the break.
max	the maxima of the upper bound of the break
...	Further arguments passed to or from other methods.

## Value

Returns no value, just map swatch of colors in geographic space!

## Author(s)

Barnabas H. Daru <[darunabas@gmail.com](mailto:darunabas@gmail.com)>

## See Also

[SpatialPolygons-class](#)

## Examples

s <- readRDS(system.file("nigeria/SR_Naija.rds", package = "phyloregion"))
plot_swatch(s, values = s$SR)
```

---

random_species	<i>Generate random species distributions in space</i>
----------------	---

---

## Description

This function generates random species distributions in geographic space as extent of occurrence range polygons based on convex hulls of random points.

## Usage

```
random_species(n, species, shp, ...)
```

## Arguments

n	vector of one or more elements to choose from, or a positive integer.
species	the desired number of species.
shp	the polygon shapefile of the study area for determining the species distributions
...	Further arguments passed to or from other methods.

## Value

A polygon shapefile of species' extent of occurrence ranges.

## Author(s)

Barnabas H. Daru <darunabas@gmail.com>

raster2comm	<i>Convert raw input distribution data to community</i>
-------------	---

---

## Description

The functions `points2comm`, `polys2comm`, `raster2comm` provide convenient interfaces to convert raw distribution data often available as point records, polygons and raster layers, respectively, to a community composition data frame at varying spatial grains and extents for downstream analyses.

## Usage

```
raster2comm(files)

polys2comm(dat, res = 1, species = "species", shp.grids = NULL, ...)

points2comm(
  dat,
  mask = NULL,
```

```

res = 1,
lon = "decimallongitude",
lat = "decimallatitude",
species = "species",
shp.grids = NULL,
...
)

```

### Arguments

files	list of raster layer objects with the same spatial extent and resolution.
dat	layers of merged maps corresponding to species polygons for polys2comm; or point occurrence data frame for points2comm, with at least three columns: <ul style="list-style-type: none"> <li>• Column 1: species (listing the taxon names)</li> <li>• Column 2: decimallongitude (corresponding to decimal longitude)</li> <li>• Column 3: decimallatitude (corresponding to decimal latitude)</li> </ul>
res	the grain size of the grid cells in decimal degrees (default).
species	a character string. The column with the species or taxon name. Default = “species”.
shp.grids	if specified, the polygon shapefile of grid cells with a column labeled “grids”.
...	Further arguments passed to or from other methods.
mask	Only applicable to points2comm. If supplied, a polygon shapefile covering the boundary of the survey region.
lon	character with the column name of the longitude.
lat	character with the column name of the latitude.

### Value

Each of these functions generate a list of two objects as follows:

- comm\_dat: (sparse) community matrix
- poly\_shp: shapefile of grid cells with the values per cell.

### See Also

[mapproject](#) for conversion of latitude and longitude into projected coordinates system. [long2sparse](#) for conversion of community data.

### Examples

```

fdirectory <- system.file("NGAplants", package="phyloregion")
files <- file.path(fdirectory, dir(fdirectory))
ras <- raster2comm(files) # Note, this function generates
# a list of two objects
head(ras[[1]])

```

```

s <- readRDS(system.file("nigeria/nigeria.rds", package="phyloregion"))
sp <- random_species(100, species=5, shp=s)
pol <- polys2comm(dat = sp, species = "species")
head(pol[[1]])

s <- readRDS(system.file("nigeria/nigeria.rds", package = "phyloregion"))

set.seed(1)
m <- data.frame(sp::spsample(s, 10000, type = "nonaligned"))
names(m) <- c("lon", "lat")
species <- paste0("sp", sample(1:1000))
m$taxon <- sample(species, size = nrow(m), replace = TRUE)

pt <- points2comm(dat = m, mask = s, res = 0.5, lon = "lon", lat = "lat",
                    species = "taxon") # Note, this generates a list of two objects
head(pt[[1]])

```

**read.community***Read in sparse community matrices***Description**

`read.community` reads in file containing occurrence data and returns a sparse matrix.

**Usage**

```
read.community(file, grids = "grids", species = "species", ...)
```

**Arguments**

- |                      |  |
|----------------------|--|
| <code>file</code>    | A file name.   |
| <code>grids</code>   | Column name of the column containing grid cells.               |
| <code>species</code> | Column name of the column containing the species / taxa names. |
| <code>...</code>     | further arguments passed to or from other methods.             |

**Value**

`read.community` returns a sparse matrix (an object of class "dgCMatrix").

**Examples**

```

df <- data.frame(grids=paste0("g", c(1,1,2,3,3)),
                  species = paste0("sp", c(1,3,2,1,4)))
df
tmp <- tempfile()

```

```
write.csv(df, tmp)
(M <- read.community(tmp) )
sparse2long(M)
unlink(tmp)
```

sdm

*Species distribution models for a range of algorithms*

## Description

This function computes species distribution models using four modelling algorithms: generalized linear models, generalized boosted models, random forests, and maximum entropy (only if `rJava` is available). Note: this is an experimental function, and may change in the future.

## Usage

```
sdm(
  x,
  pol = NULL,
  predictors = NULL,
  blank = NULL,
  res = 1,
  tc = 2,
  lr = 0.001,
  bf = 0.75,
  n.trees = 50,
  step.size = n.trees,
  k = 5,
  herbarium.rm = TRUE,
  n_points = 30
)
```

## Arguments

<code>x</code>	A data frame containing the species occurrences and geographic coordinates. Column 1 labeled as "species", column 2 "lon", column 3 "lat".
<code>pol</code>	A polygon shapefile specifying the boundary to restrict the prediction. If not specified, a minimum convex polygon is estimated using the input data frame of species occurrences.
<code>predictors</code>	RasterStack of environmental descriptors on which the models will be projected
<code>blank</code>	A blank raster upon which the prediction layer is aggregated to.
<code>res</code>	Desired resolution of the predicted potential species distribution (if blank raster is not specified).
<code>tc</code>	Integer. Tree complexity. Sets the complexity of individual trees
<code>lr</code>	Learning rate. Sets the weight applied to individual trees

bf	Bag fraction. Sets the proportion of observations used in selecting variables
n.trees	Number of initial trees to fit. Set at 50 by default
step.size	Number of trees to add at each cycle
k	Number of groups
herbarium.rm	Logical, remove points within 50 km of herbaria.
n_points	Minimum number of points required to successfully run a species distribution model

### Value

A list with the following objects:

- ensemble\_raster The ensembled raster that predicts the potential species distribution.
- ensemble\_AUC The median AUCs of models.
- data The dataframe that was used to implement the model.
- indiv\_models Raster layers for the separate models that predict the potential species distribution.
- single\_AUCs The AUCs for the separate models.

### References

Phillips, S.J., Anderson, R.P. & Schapire, R.E. (2006) Maximum entropy modeling of species geographic distributions. *Ecological Modelling* **190**: 231-259.

### Examples

```
library(raster)
# get predictor variables
f <- list.files(path=paste(system.file(package="phyloregion"), '/ex', sep=''),
                 pattern='.tif', full.names=TRUE )
preds <- stack(f)
#plot(preds)
# get species occurrences
d <- read.csv(system.file("ex/Bombax.csv", package="phyloregion"))

# fit ensemble model for four algorithms
mod <- sdm(d, predictors = preds)
```

---

<code>selectbylocation</code>	<i>Select polygon features from another layer and adds polygon attributes to layer</i>
-------------------------------	--

---

## Description

The `selectbylocation` function selects features based on their location relative to features in another layer.

## Usage

```
selectbylocation(x, y)
```

## Arguments

- |                |  |
|----------------|--|
| <code>x</code> | source layer of the class <code>SpatialPolygonsDataFrame</code> or <code>SpatialPointsDataFrame</code> |
| <code>y</code> | Target layer or mask extent to subset from.  |

## Value

A spatial polygons or spatial points object pruned to the extent of the target layer.

## Examples

```
library(raster)
file <- system.file("nigeria/nigeria.rds", package = "phyloregion")
d <- readRDS(file)
e <- extent(d)

set.seed(1)
m <- data.frame(lon = runif(1000, e[1], e[2]),
                 lat = runif(1000, e[3], e[4]),
                 sites = seq(1000))
coordinates(m) <- ~lon + lat
z <- selectbylocation(m, d)
plot(d)
points(m, col = "blue", pch = "+")
points(z, col = "red", pch = "+")
```

select\_linkage

*Cluster algorithm selection and validation*

## Description

This function contrasts different hierarchical clustering algorithms on the phylogenetic beta diversity matrix for degree of data distortion using Sokal & Rohlf's (1962) cophenetic correlation coefficient.

## Usage

```
select_linkage(x)
```

## Arguments

x a numeric matrix, data frame or "dist" object.

## Value

- A numeric value corresponding to the good clustering algorithm for the distance matrix
- If plot = TRUE, a barplot of cophenetic correlation for all the clustering algorithms is drawn.

## References

Sokal, R.R. & Rohlf, F.J. (1962) The comparison of dendograms by objective methods. *Taxon* **11**: 33–40.

## Examples

```
data(africa)
tree <- africa$phylo
bc <- beta_diss(africa$comm)
y <- select_linkage(bc[[1]])
barplot(y, horiz = TRUE, las = 1)
```

timeslice

*Slice phylogenetic tree at various time depths*

## Description

This function slices a dated phylogenetic tree at successive time depths back in time by collapsing younger phylogenetic branches into older ones to infer the origins of species assemblages.

## Usage

```
timeslice(phy, n = 0.2, collapse = FALSE, ...)
```

**Arguments**

phy	A dated phylogenetic tree as an object of class “phylo”.
n	Time depth to slice the phylogenetic tree (often in millions of years for dated trees).
collapse	Logical, collapse internal edges with zero edge length.
...	arguments passed among methods.

**Value**

A tree with the phylogenetic structure removed at the specified time depth

**References**

Daru, B.H., van der Bank, M. & Davies, T.J. (2018) Unravelling the evolutionary origins of biogeographic assemblages. *Diversity and Distributions* **24**: 313–324.

**Examples**

```
library(ape)

set.seed(1)
tree <- rcoal(50)
x <- timeslice(tree, .5)

old.par <- par(no.readonly = TRUE)
par(mfrow = c(1, 2))
plot(tree)
axisPhylo()
plot(x)
axisPhylo()
par(old.par)
```

**weighted\_endemism**      *Measure the distribution of narrow-ranged or endemic species.*

**Description**

`weighted_endemism` is species richness inversely weighted by species ranges.

**Usage**

```
weighted_endemism(x)
```

**Arguments**

- x A (sparse) community matrix.

**Value**

A data frame of species traits by site.

**References**

- Daru, B.H., Farooq, H., Antonelli, A. & Faurby, S. (2020) Endemism patterns are scale dependent. *Nature Communications* **11** : 2115.

**Examples**

```
library(raster)
data(africa)
Endm <- weighted_endemism(africa$comm)
m <- merge(africa$polys, data.frame(grids=names(Endm), WE=Endm), by="grids")
m <- m[!is.na(m@data$WE),]

plot_swatch(m, values = m$WE,
           col = hcl.colors(20, palette = "Blue-Red 3", rev=FALSE))
```
