Package 'seededlda'

March 28, 2022

Type Package

Title Seeded-LDA for Topic Modeling

Version 0.8.1

Description Implements the seeded-
LDA model (Lu, Ott, Cardie & Tsou 2010) <doi:10.1109/ICDMW.2011.125> us-
ing the quanteda package and the GibbsLDA++ library for semisupervised topic modeling.
Seeded-LDA allows users to pre-define topics with keywords to perform theory-driven analy-
sis of textual data in social sciences and humanities (Watan-
abe & Zhou 2020) <doi:10.1177/0894439320907027>.

R topics documented:

divergence 2
terms 2
textmodel_lda 3
topics 5

Index **6**

`divergence` *Optimize the number of topics*

Description

These functions help users to find the optimal number of topics for LDA.

Usage

```
divergence(x)
```

Arguments

`x`	a LDA model fitted by `textmodel_seededlda()` or `textmodel_lda()`

Details

`divergence()` computes the average Kullback–Leibler distance between all the pairs of topic vectors in `x$phi`. The divergence score maximizes when the chosen number of topic `k` is optimal (Deveaud et al., 2014).

References

Deveaud, Romain et al. (2014). "Accurate and Effective Latent Concept Modeling for Ad Hoc Information Retrieval". doi:10.3166/DN.17.1.61-84. *Document Numérique*.

`terms` *Extract most likely terms*

Description

`terms()` returns the most likely terms, or words, for topics based on the `phi` parameter.

Usage

```
terms(x, n = 10)
```

Arguments

`x`	a LDA model fitted by `textmodel_seededlda()` or `textmodel_lda()`
`n`	number of terms to be extracted

Details

Users can access the original matrix `x$phi` for likelihood scores.

textmodel_lda *Semisupervised Latent Dirichlet allocation*

Description

`textmodel_seededlda()` implements semisupervised Latent Dirichlet allocation (seeded-LDA). The estimator's code adopted from the GibbsLDA++ library (Xuan-Hieu Phan, 2007). `textmodel_seededlda()` allows users to specify topics using a seed word dictionary.

Usage

```
textmodel_lda(
  x,
  k = 10,
  max_iter = 2000,
  alpha = NULL,
  beta = NULL,
  model = NULL,
  verbose = quanteda_options("verbose")
)

textmodel_seededlda(
  x,
  dictionary,
  valuetype = c("glob", "regex", "fixed"),
  case_insensitive = TRUE,
  residual = 0,
  weight = 0.01,
  max_iter = 2000,
  alpha = NULL,
  beta = NULL,
  ...,
  verbose = quanteda_options("verbose")
)
```

Arguments

`x`	the dfm on which the model will be fit
`k`	the number of topics; determined automatically by the number of keys in `dictionary` in `textmodel_seededlda()`.
`max_iter`	the maximum number of iteration in Gibbs sampling.
`alpha`	the value to smooth topic-document distribution; defaults to `alpha = 50 / k`.
`beta`	the value to smooth topic-word distribution; defaults to `beta = 0.1`.
`model`	a fitted LDA model; if provided, `textmodel_lda()` inherits parameters from an existing model. See details.

verbose	logical; if TRUE print diagnostic information during fitting.
dictionary	a quanteda::dictionary() with seed words that define topics.
valuetype	see quanteda::valuetype
case_insensitive	see quanteda::valuetype
residual	the number of undefined topics. They are named "other" by default, but it can be changed via base::options(slda_residual_name).
weight	pseudo count given to seed words as a proportion of total number of words in x.
...	passed to quanteda::dfm_trim to restrict seed words based on their term or document frequency. This is useful when glob patterns in the dictionary match too many words.

Details

To predict topics of new documents (i.e. out-of-sample), first, create a new LDA model from a existing LDA model passed to model in textmodel_lda(); second, apply topics() to the new model. The model argument takes objects created either by textmodel_lda() or textmodel_seededlda().

Value

textmodel_seededlda() and textmodel_lda() returns a list of model parameters. theta is the distribution of topics over documents; phi is the distribution of words over topics. alpha and beta are the small constant added to the frequency of words to estimate theta and phi, respectively, in Gibbs sampling. Other elements in the list subject to change.

require(seededlda)
require(quanteda)

data("data_corpus_moviereviews", package = "quanteda.textmodels")
corp <- head(data_corpus_moviereviews, 500)
toks <- tokens(corp, remove_punct = TRUE, remove_symbols = TRUE, remove_number = TRUE)
dfmt <- dfm(toks) %>%
    dfm_remove(stopwords('en'), min_nchar = 2) %>%
```

```
    dfm_trim(min_termfreq = 0.90, termfreq_type = "quantile",
             max_docfreq = 0.1, docfreq_type = "prop")

# unsupervised LDA
lda <- textmodel_lda(head(dfmt, 450), 6)
terms(lda)
topics(lda)
lda2 <- textmodel_lda(tail(dfmt, 50), model = lda) # new documents
topics(lda2)

# semisupervised LDA
dict <- dictionary(list(people = c("family", "couple", "kids"),
                        space = c("alien", "planet", "space"),
                        moster = c("monster*", "ghost*", "zombie*"),
                        war = c("war", "soldier*", "tanks"),
                        crime = c("crime*", "murder", "killer")))
slda <- textmodel_seededlda(dfmt, dict, residual = TRUE, min_termfreq = 10)
terms(slda)
topics(slda)
```

`topics` *Extract most likely topics*

Description

`topics()` returns the most likely topics for documents based on the `theta` parameter.

Usage

```
topics(x)
```

Arguments

x	a LDA model fitted by `textmodel_seededlda()` or `textmodel_lda()`

Details

Users can access the original matrix `x$theta` for likelihood scores; run `max.col(x$theta)` to obtain the same result as `topics(x)`.
